# Author(s)

Matthias Kohl https://www.stamats.de

Maintainer: Matthias Kohl <matthias.kohl@stamats.de>

C٧

# Description

The functions compute coefficient of variation (CV) as well as two robust versions of the CV.

# Usage

CV(x, na.rm = FALSE)	
<pre>medCV(x, na.rm = FALSE,</pre>	<pre>constant = 1/qnorm(0.75))</pre>
<pre>iqrCV(x, na.rm = FALSE,</pre>	type = 7, constant = $2*qnorm(0.75)$ )

# Arguments

х	numeric vector with positive numbers.
na.rm	logical. Should missing values be removed?
type	an integer between 1 and 9 selecting one of nine quantile algorithms; for more details see quantile.
constant	standardizing contant; see mad and sIQR, respectively.

# Details

The functions compute the (classical) CV as well as two robust variants.

medCV uses the (standardized) MAD instead of SD and median instead of mean.

iqrCV uses the (standardized) IQR instead of SD and median instead of mean.

# Value

CV value.

# Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

# References

C.N.P.G. Arachchige, L.A. Prendergast and R.G. Staudte. Robust analogues to the Coefficient of Variation. https://arxiv.org/abs/1907.01110.

#### Examples

```
## 5% outliers
out <- rbinom(100, prob = 0.05, size = 1)
sum(out)
x <- (1-out)*rnorm(100, mean = 10, sd = 2) + out*25
CV(x)
medCV(x)
iqrCV(x)</pre>
```

fiveNS

#### Five-Number Summaries

# Description

Function to compute five-number summaries (minimum, 1st quartile, median, 3rd quartile, maximum)

# Usage

fiveNS(x, na.rm = TRUE, type = 7)

# Arguments

Х	numeric vector
na.rm	logical; remove NA before the computations.
type	an integer between 1 and 9 selecting one of nine quantile algorithms; for more
	details see quantile.

# Details

In contrast to fivenum the functions computes the first and third quartile using function quantile.

# Value

A numeric vector of length 5 containing the summary information.

# Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

# See Also

fivenum, quantile

#### Examples

```
x <- rnorm(100)
fiveNS(x)
fiveNS(x, type = 2)
fivenum(x)</pre>
```

4

glog

#### Description

The functions compute the generalized logarithm, which is more or less identical to the area hyperbolic sine, and their inverse; see details.

# Usage

```
glog(x, base = exp(1))
glog10(x)
glog2(x)
inv.glog(x, base = exp(1))
inv.glog10(x)
inv.glog2(x)
```

#### Arguments

х	a numeric or complex vector.
base	a positive or a positive or complex number: the base with respect to which logarithms are computed. Defaults to $e=exp(1)$ .

#### Details

The function computes

$$\log(x + \sqrt{x^2 + 1}) - \log(2)$$

where the first part corresponds to the area hyperbolic sine. Subtracting log(2) makes the function asymptotically identical to the logarithm.

#### Value

A vector of the same length as x containing the transformed values.

#### Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

```
curve(log, from = -3, to = 5)
curve(glog, from = -3, to = 5, add = TRUE, col = "orange")
legend("topleft", fill = c("black", "orange"), legend = c("log", "glog"))
curve(log10(x), from = -3, to = 5)
curve(glog10(x), from = -3, to = 5, add = TRUE, col = "orange")
legend("topleft", fill = c("black", "orange"), legend = c("log10", "glog10"))
```

```
inv.glog(glog(10))
inv.glog(glog(10, base = 3), base = 3)
inv.glog10(glog10(10))
inv.glog2(glog2(10))
```

illustrate.boxplot Illustrate Box-and-Whisker Plots

# Description

Function to illustrate the computation of box-and-whisker plots.

#### Usage

```
illustrate.boxplot(x)
```

# Arguments ×

numeric vector

# Details

The function visualizes the computation of box-and-whisker plots.

# Value

An invisible object of class ggplot.

# Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

# See Also

boxplot, geom\_boxplot

# Examples

```
set.seed(123)
illustrate.boxplot(rt(50, df = 5))
illustrate.boxplot(rnorm(50, mean = 3, sd = 2))
```

6

illustrate.quantile Illustrate Quantiles

# Description

Function to illustrate the computation of quantiles.

# Usage

illustrate.quantile(x, alpha, type)

#### Arguments

х	numeric vector
alpha	numeric value in the interval $(0,1)$ .
type	integer values between 1 and 9 selecting one or several of nine quantile algo- rithms; for more details see quantile. If missing, all nine are computed.

# Details

The function visualizes the computation of alpha-quantiles.

#### Value

An invisible object of class ggplot.

# Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

#### See Also

quantile

```
x <- 1:10
illustrate.quantile(x, alpha = 0.15)
illustrate.quantile(x, alpha = 0.5)
illustrate.quantile(x, alpha = 0.8, type = 2)
illustrate.quantile(x, alpha = 0.8, type = c(2, 7))
illustrate.quantile(x = rnorm(20), alpha = 0.95)
illustrate.quantile(x = rnorm(21), alpha = 0.95)
```

IQrange

### Description

Computes (standardized) interquartile range of the x values.

#### Usage

IQrange(x, na.rm = FALSE, type = 7)
sIQR(x, na.rm = FALSE, type = 7, constant = 2\*qnorm(0.75))

#### Arguments

х	a numeric vector.
na.rm	logical. Should missing values be removed?
type	an integer between 1 and 9 selecting one of nine quantile algorithms; for more details see quantile.
constant	standardizing contant; see details below.

#### Details

This function IQrange computes quartiles as IQR(x) = quantile(x, 3/4) - quantile(x, 1/4). The function is identical to function IQR. It was added before the type argument was introduced to function IQR in 2010 (r53643, r53644).

For normally N(m, 1) distributed X, the expected value of IQR(X) is 2\*qnorm(3/4) = 1.3490, i.e., for a normal-consistent estimate of the standard deviation, use IQR(x) / 1.349. This is implemented in function sIQR (standardized IQR).

#### Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

#### References

IQrange(rivers, type = 5)
## standardized IQR
sIQR(rivers)
## right-skewed data distribution
sd(rivers)
mad(rivers)
## for normal data
x <- rnorm(100)</pre>
sd(x)
sIQR(x)
mad(x)
```

meanAD

The Mean Absolute Deviation

# Description

Computes (standardized) mean absolute deviation.

#### Usage

meanAD(x, na.rm = FALSE, constant = sqrt(pi/2))

#### Arguments

Х	a numeric vector.
na.rm	logical. Should missing values be removed?
constant	standardizing contant; see details below.

#### Details

The mean absolute deviation is a consistent estimator of  $\sqrt{2/\pi\sigma}$  for the standard deviation of a normal distribution. Under minor deviations of the normal distributions its asymptotic variance is smaller than that of the sample standard deviation (Tukey (1960)).

It works well under the assumption of symmetric, where mean and median coincide. Under the normal distribution it's about 18% more efficient (asymptotic relative efficiency) than the median absolute deviation ((1/qnorm(0.75))/sqrt(pi/2)) and about 12% less efficient than the sample standard deviation (Tukey (1960)).

## worst case
optimize(ARE, interval = c(0,1), maximum = TRUE)
```

melt.long

#### Description

The function transforms a given data.frame form wide to long form.

# Usage

melt.long(data, select, group)

#### Arguments

data	data.frame that shall be transformed.
select	optional integer vector to select a subset of the columns of data.
group	optional vector to include an additional grouping in the output; for more details see examples below.

# Details

The function transforms a given data.frame form wide to long form. This is for example useful for plotting with ggplot2.

#### Value

data.frame in long form.

#### Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

```
library(ggplot2)
## some random data
test <- data.frame(x = rnorm(10), y = rnorm(10), z = rnorm(10))
test.long <- melt.long(test)
test.long
ggplot(test.long, aes(x = variable, y = value)) +
geom_boxplot(aes(fill = variable))
## introducing an additional grouping variable
group <- factor(rep(c("a","b"), each = 5))
test.long.gr <- melt.long(test, select = 1:2, group = group)
test.long.gr
ggplot(test.long.gr, aes(x = variable, y = value, fill = group)) +
geom_boxplot()</pre>
```

#### qboxplot

# Description

Produce box-and-whisker plot(s) of the given (grouped) values. In contrast to boxplot quartiles are used instead of hinges (which are not necessarily quartiles) the rest of the implementation is identical to boxplot.

#### Usage

#### Arguments

formula	a formula, such as y ~ grp, where y is a numeric vector of data values to be split into groups according to the grouping variable grp (usually a factor).
data	a data.frame (or list) from which the variables in formula should be taken.
subset	an optional vector specifying a subset of observations to be used for plotting.
na.action	a function which indicates what should happen when the data contain NAs. The default is to ignore missing values in either the response or the group.
x	for specifying data from which the boxplots are to be produced. Either a numeric vector, or a single list containing such vectors. Additional unnamed arguments specify further data as separate vectors (each corresponding to a component boxplot). NAs are allowed in the data.
	For the formula method, named arguments to be passed to the default method. For the default method, unnamed arguments are additional data vectors (unless x is a list when they are ignored), and named arguments are arguments and graphical parameters to be passed to bxp in addition to the ones given by argument pars (and override those in pars).
range	this determines how far the plot whiskers extend out from the box. If range is positive, the whiskers extend to the most extreme data point which is no more than range times the interquartile range from the box. A value of zero causes the whiskers to extend to the data extremes.
width	a vector giving the relative widths of the boxes making up the plot.

qboxplot
----------

varwidth	if varwidth is TRUE, the boxes are drawn with widths proportional to the square- roots of the number of observations in the groups.
notch	if notch is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is 'strong evidence' that the two medians differ (Chambers <i>et al.</i> , 1983, p. 62). See boxplot.stats for the calculations used.
outline	if outline is not true, the outliers are not drawn (as points whereas S+ uses lines).
names	group labels which will be printed under each boxplot. Can be a character vector or an expression (see plotmath).
boxwex	a scale factor to be applied to all boxes. When there are only a few groups, the appearance of the plot can be improved by making the boxes narrower.
staplewex	staple line width expansion, proportional to box width.
outwex	outlier line width expansion, proportional to box width.
plot	if TRUE (the default) then a boxplot is produced. If not, the summaries which the boxplots are based on are returned.
border	an optional vector of colors for the outlines of the boxplots. The values in border are recycled if the length of border is less than the number of plots.
col	if col is non-null it is assumed to contain colors to be used to colour the bodies of the box plots. By default they are in the background colour.
log	character indicating if x or y or both coordinates should be plotted in log scale.
pars	a list of (potentially many) more graphical parameters, e.g., boxwex or outpch; these are passed to bxp (if plot is true); for details, see there.
horizontal	logical indicating if the boxplots should be horizontal; default FALSE means vertical boxes.
add	logical, if true add boxplot to current plot.
at	numeric vector giving the locations where the boxplots should be drawn, partic- ularly when add = TRUE; defaults to 1:n where n is the number of boxes.
type	an integer between 1 and 9 selecting one of nine quantile algorithms; for more details see quantile.

# Details

The generic function qboxplot currently has a default method (qboxplot.default) and a formula interface (qboxplot.formula).

If multiple groups are supplied either as multiple arguments or via a formula, parallel boxplots will be plotted, in the order of the arguments or the order of the levels of the factor (see factor).

Missing values are ignored when forming boxplots.

### Value

List with the following components:

stats a matrix, each column contains the extreme of the lower whisker, the lower hinge, the median, the upper hinge and the extreme of the upper whisker for one group/plot. If all the inputs have the same class attribute, so will this component.

n	a vector with the number of observations in each group.
conf	a matrix where each column contains the lower and upper extremes of the notch.
out	the values of any data points which lie beyond the extremes of the whiskers.
group	a vector of the same length as out whose elements indicate to which group the outlier belongs.
names	a vector of names for the groups.

       fill = c("yellow", "orange"))
par(op)
```

DOAT IOI DIAIISIICS	qbxp.stats	<b>Box Plot Statistics</b>
---------------------	------------	----------------------------

#### Description

This functions works identical to boxplot.stats. It is typically called by another function to gather the statistics necessary for producing box plots, but may be invoked separately.

#### Usage

gbxp.stats(x, coef = 1.5, do.conf = TRUE, do.out = TRUE, type = 7)

#### Arguments

x	a numeric vector for which the boxplot will be constructed (NAs and NaNs are allowed and omitted).
coef	it determines how far the plot 'whiskers' extend out from the box. If coef is positive, the whiskers extend to the most extreme data point which is no more than coef times the length of the box away from the box. A value of zero causes the whiskers to extend to the data extremes (and no outliers be returned).
do.conf	logical; if FALSE, the conf component will be empty in the result.
do.out	logical; if FALSE, out component will be empty in the result.
type	an integer between 1 and 9 selecting one of nine quantile algorithms; for more details see quantile.

#### Details

The notches (if requested) extend to +/-1.58 IQR/sqrt(n). This seems to be based on the same calculations as the formula with 1.57 in Chambers *et al.* (1983, p. 62), given in McGill *et al.* (1978, p. 16). They are based on asymptotic normality of the median and roughly equal sample sizes for the two medians being compared, and are said to be rather insensitive to the underlying distributions of the samples. The idea appears to be to give roughly a 95% confidence interval for the difference in two medians.

# Value

List with named components as follows:

stats	a vector of length 5, containing the extreme of the lower whisker, the first quar- tile, the median, the third quartile and the extreme of the upper whisker.
n	the number of non-NA observations in the sample.
conf	the lower and upper extremes of the 'notch' (if(do.conf)). See the details.
out	the values of any data points which lie beyond the extremes of the whiskers $(if(do.out))$ .

Note that \$stats and \$conf are sorted in *increasing* order, unlike S, and that \$n and \$out include any +- Inf values.

#### Seven-Number Summaries

# Description

Function to compute seven-number summaries (minimum, 1st octile, 1st quartile, median, 3rd quartile, 7th octile, maximum)

#### Usage

sevenNS(x, na.rm = TRUE, type = 7)

# Arguments

Х	numeric vector
na.rm	logical; remove NA before the computations.
type	an integer between 1 and 9 selecting one of nine quantile algorithms; for more details see quantile.

# Details

In contrast to Tukey (1977) who proposes hinges and eighths, we use function quantile.

# Value

A numeric vector of length 7 containing the summary information.

#### Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

# References

Tukey, J.W. (1977). Exploratory Data Analysis. Section 2G.

# See Also

fivenum, quantile

#### Examples

```
x <- rnorm(100)
sevenNS(x)
sevenNS(x, type = 2)</pre>
```

simCorVars

Simulate correlated variables.

# Description

The function simulates a pair of correlated variables.

#### Usage

simCorVars(n, r, mu1 = 0, mu2 = 0, sd1 = 1, sd2 = 1, plot = TRUE)

# Arguments

n	integer: sample size.
r	numeric: correlation.
mu1	numeric: mean of first variable.
mu2	numeric: mean of second variable.
sd1	numeric: SD of first variable.
sd2	numeric: SD of second variable.
plot	logical: generate scatter plot of the variables.

#### Details

The function is mainly for teaching purposes and simulates n observations from a pair of normal distributed variables with correlation r.

By specifying plot = TRUE a scatter plot of the data is generated.

## Value

data.frame with entries Var1 and Var2

#### Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

18

#### skippedMean

#### Examples

```
set.seed(123)
res <- simCorVars(n = 100, r = 0.8)
cor(res$Var1, res$Var2)
colMeans(res)
apply(res, 2, sd)
set.seed(123)
res <- simCorVars(n = 100, r = 0.8, mu1 = -1, mu2 = 1, sd1 = 2, sd2 = 0.5)
cor(res$Var1, res$Var2)
colMeans(res)
apply(res, 2, sd)</pre>
```

skippedMean

Hyber-type Skipped Mean and SD

# Description

Computes Huper-type Skipped Mean and SD.

#### Usage

```
skippedMean(x, na.rm = FALSE, constant = 3.0)
skippedSD(x, na.rm = FALSE, constant = 3.0)
```

#### Arguments

х	a numeric vector.
na.rm	logical. Should missing values be removed?
constant	multiplier for outlier identification; see details below.

### Details

The Huber-type skipped mean and is very close to estimator X42 of Hampel (1985), which uses 3.03 x MAD. Quoting Hampel et al. (1986), p. 69, the X42 estimator is "frequently quite reasonable, according to present preliminary knowledge".

For computing the Huber-type skipped mean, one first computes median and MAD. In the next step, all observations outside the interval [median - constant x MAD, median + constant x MAD] are removed and arithmetic mean and sample standard deviation are computed on the remaining data.

x <- rnorm(100)
mean(x)
median(x)
skippedMean(x)
sd(x)
mad(x)
skippedSD(x)
## Tukey's gross error model
## (1-eps)*Norm(mean, sd = sigma) + eps*Norm(mean, sd = 3*sigma)
ind <- rbinom(100, size = 1, prob = 0.1)
x.err <- (1-ind) *x + ind *rnorm(100, sd = 3)
mean(x.err)
median(x.err)
skippedMean(x.err)
sd(x.err)
mad(x.err)
skippedSD(x.err)
```

SMD

Compute Standardized Mean Difference (SMD)

#### Description

The function computes the standardized mean difference, where a bias correction can be applied.

#### Usage

```
SMD(x, y, bias.cor = TRUE, var.equal = FALSE, na.rm = FALSE)
```

# SMD

# Arguments

х	numeric vector, data of group 1.
У	numeric vector, data of group 2.
bias.cor	a logical variable indicating whether a bias correction should be performed.
var.equal	a logical variable indicating whether to treat the two variances as being equal. If TRUE then the pooled variance is used to estimate the variance otherwise the Welch-Satterthwaite approximation is used.
na.rm	logical. Should missing values be removed?

# Details

The function compute the (bias-corrected) standardized mean difference.

If bias.cor = FALSE and var.equal = TRUE, the result corresponds to Cohen's d (Cohen (1988)).

If bias.cor = TRUE and var.equal = TRUE, the result corresponds to Hedges' g (Hedges (1981)).

If bias.cor = FALSE and var.equal = FALSE, the result is closely related to the test statistic of Welch's t test (Aoki (2020)).

If bias.cor = TRUE and var.equal = FALSE, the result corresponds to Aoki's e (Aoki (2020)) which incorporates a Welch-Satterthwaite approximation in combination with a bias correction.

#### Value

SMD value.

```

SNR

Compute SNR

#### Description

The functions compute the signal to noise ration (SNR) as well as two robust versions of the SNR.

#### Usage

SNR(x, na.rm = FALSE)
medSNR(x, na.rm = FALSE, constant = 1/qnorm(0.75))
iqrSNR(x, na.rm = FALSE, type = 7, constant = 2\*qnorm(0.75))

#### Arguments

х	numeric vector.
na.rm	logical. Should missing values be removed?
type	an integer between 1 and 9 selecting one of nine quantile algorithms; for more details see quantile.
constant	standardizing contant; see mad and sIQR, respectively.

# Details

The functions compute the (classical) SNRas well as two robust variants. medSNR uses the (standardized) MAD instead of SD and median instead of mean. iqrSNR uses the (standardized) IQR instead of SD and median instead of mean.

# Value

SNR value.

# Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

# Examples

```
## 5% outliers
out <- rbinom(100, prob = 0.05, size = 1)
sum(out)
x <- (1-out)*rnorm(100, mean = 10, sd = 2) + out*25
SNR(x)
medSNR(x)
iqrSNR(x)</pre>
```

thyroid

*Plot TSH, fT3 and fT4 with respect to reference range.* 

#### Description

The function computes and plots TSH, fT3 and fT4 values with respect to the provided reference range.

# Usage

```
thyroid(TSH, fT3, fT4, TSHref, fT3ref, fT4ref)
```

# Arguments

TSH	numeric vector of length 1: measured TSH concentration.
fT3	numeric vector of length 1: measured fT3 concentration.
fT4	numeric vector of length 1: measured fT4 concentration.
TSHref	numeric vector of length 2: reference range TSH.
fT3ref	numeric vector of length 2: reference range fT3.
fT4ref	numeric vector of length 2: reference range fT4.

#### Details

A simple function that computes the relative values of the measured values with respect to the provided reference range and visualizes the values using a barplot. Relative values between 40% and 60% are marked as O.K..

#### Value

Invisible data.frame with the relative values.

#### Author(s)

Matthias Kohl <Matthias.Kohl@stamats.de>

#### Examples

```
thyroid(TSH = 1.5, fT3 = 2.5, fT4 = 14, TSHref = c(0.2, 3.0),
fT3ref = c(1.7, 4.2), fT4ref = c(7.6, 15.0))
```

transformations New Transformations for Use with ggplot2 Package

#### Description

The functions generate new transformations for the generalized logarithm and the negative logarithm that can be used for transforming the axes in ggplot2 plots.

#### Usage

```
glog_trans(base = exp(1))
glog10_trans()
glog2_trans()
scale_y_glog(...)
scale_x_glog(...)
scale_y_glog10(...)
scale_x_glog10(...)
scale_y_glog2(...)
scale_x_glog2(...)
scale_y_log(...)
scale_x_log(...)
scale_y_log2(...)
scale_x_log2(...)
neglog_breaks(n = 5, base = 10)
neglog_trans(base = exp(1))
neglog10_trans()
neglog2_trans()
scale_y_neglog(...)
scale_x_neglog(...)
scale_y_neglog10(...)
scale_x_neglog10(...)
scale_y_neglog2(...)
scale_x_neglog2(...)
```

#### Arguments

base	a positive or a positive or complex number: the base with respect to which
	generalized and negative logarithms are computed. Defaults to e=exp(1).
	Arguments passed on to scale_(xly)_continuous.
n	desired number of breaks.

## transformations

#### Details

The functions can be used to transform axes in ggplot2 plots. The implementation is analogous to e.g. scale\_y\_log10.

The negative logarithm is for instance of use in case of p values (e.g. volcano plots),

The functions were adapted from packages scales and ggplot2.

# Value

A transformation.

zscore

Compute z-Scores

# Description

The functions compute the classical z-score as well as two robust versions of z-scores.

# Usage

zscore(x, na.rm = FALSE)
medZscore(x, na.rm = FALSE, constant = 1/qnorm(0.75))
iqrZscore(x, na.rm = FALSE, type = 7, constant = 2\*qnorm(0.75))

#### Arguments

х	numeric vector with positive numbers.
na.rm	logical. Should missing values be removed?
type	an integer between 1 and 9 selecting one of nine quantile algorithms; for more details see quantile.
constant	standardizing contant; see mad and sIQR, respectively.

# Details

The functions compute the (classical) zscore as well as two robust variants. medZscore uses the (standardized) MAD instead of SD and median instead of mean. iqrZscore uses the (standardized) IQR instead of SD and median instead of mean.

# Value
