

# Package ‘exact.n’

November 9, 2023

**Type** Package

**Title** Exact Samples Sizes and Inference for Clinical Trials with Binary Endpoint

**Version** 1.1.1

**Date** 2023-11-08

**Author** Chris J. Lloyd

**Maintainer** Chris J. Lloyd <c.lloyd@mbs.edu>

**Description** Allows the user to determine minimum sample sizes that achieve target size and power at a specified alternative. For more information, see “Exact samples sizes for clinical trials subject to size and power constraints” by Lloyd, C.J. (2022) Preprint <[doi:10.13140/RG.2.2.11828.94085](https://doi.org/10.13140/RG.2.2.11828.94085)>.

**License** GPL-2

**Depends** R(>= 3.5)

**Imports** graphics, stats, httr

**Encoding** UTF-8

**RoxygenNote** 7.2.3

**NeedsCompilation** no

**Repository** CRAN

**Date/Publication** 2023-11-09 02:30:02 UTC

**fetch.data**

*Download a target power library*

---

**Description**

Function downloads one of 85 power libraries from chrislloyd.com.au. The libraries are all four column matrices with roughly 20 million rows and will be around 1.4Gb within R. Download should take roughly a minute. The object will have a name of the form LIB.alpha.delta.Rdata.

**Usage**

```
fetch.data(alpha, delta, prin = FALSE)
```

**Arguments**

alpha	value of nominal size of test
delta	value of clinically relevant difference
prin	If TRUE, error and/or warning messages are printed.

**Value**

No return value. A library object will appear in the global environment.

**Author(s)**

Chris J. Lloyd

[doi:10.13140/RG.2.2.11828.94085](https://doi.org/10.13140/RG.2.2.11828.94085)

**Examples**

```
#'  
## Not run:  
fetch.data(alpha=0.05,delta=0.10)  
# Object LIB.a050.d10 will appear with 83,289,960 elements  
  
## End(Not run)
```

---

inference	<i>Approximate and exact tests for single data set</i>
-----------	--

---

## Description

For a single provided data sets ( $y_0, n_0, y_1, n_1$ ) calculate approximate and quasi-exact test statistics of the null value  $p_1-p_0=\psi$ .

## Usage

```
inference(y0, n0, y1, n1, psi = 0, sided = 1, dec.places = 4)
```

## Arguments

<code>y0</code>	number of successes for control
<code>n0</code>	control sample size
<code>y1</code>	number of successes for treatment
<code>n1</code>	treatment sample size
<code>psi</code>	null value of risk difference $p_1-p_0$
<code>sided</code>	1-sided or 2-sided test
<code>dec.places</code>	decimal places of output T and P values

## Value

List with elements

<code>y</code>	the data vector $y_0, y_1$
<code>n</code>	the sample size vector $n_0, n_1$
<code>approx</code>	approximate T-value and p-value
<code>quasi.exact</code>	quasi.exact T-value and p-value
<code>pmle</code>	profile maximum likelihood estimate of baseline probability
<code>psi</code>	null value of $p_1-p_0$

## Author(s)

Chris J. Lloyd

## References

C.J. Lloyd (2022) Exact samples sizes for clinical trials subject to size and power constraints.  
Preprint. [doi:10.13140/RG.2.2.11828.94085](https://doi.org/10.13140/RG.2.2.11828.94085)

## Examples

```
y0=25
y1=41
n0=65
n1=82
# Non-inferiority test of p1-p0>-0.1. Evidence is strong.
inference(y0,n0,y1,n1,psi=-0.1)
```

**main.function**

*Provide sample size solutions for target size and power.*

## Description

Function gives smallest values for n1 as function of n0 that achieve target size and power.

## Usage

```
main.function(
  alpha,
  delta,
  beta = 0.75,
  p0 = 0.5,
  type = 2,
  plt = FALSE,
  out = (-1),
  b.lim = 5,
  prin = TRUE
)
```

## Arguments

alpha	value of nominal size of test
delta	value of clinically relevant difference
beta	scalar target for power
p0	single value or range of values for baseline probability
type	type of maximisation (see n1.get documentation)
plt	If TRUE, plot n1 solutions versus
out	More solutions output if out > 0 than out < 0 (see details)
b.lim	maximum imbalance of sample sizes
prin	If TRUE, error messages will be printed.

## Details

If out > 0 all solutions (including n1=Inf) are returned. If out=0, infinite values are suppressed. If out < 0, only output satisfying the balance criterion are output.

## Value

list with elements n0 and n1

## Note

The appropriate data file needs to have been downloaded corresponding to the desired value of alpha and delta. This can be done with the fetch.data() function.

## Author(s)

Chris J. Lloyd

## References

C.J. Lloyd (2022) Exact samples sizes for clinical trials subject to size and power constraints. Preprint. [doi:10.13140/RG.2.2.11828.94085](https://doi.org/10.13140/RG.2.2.11828.94085)

## Examples

```
# We are interested in designs with power at least 0.75 when exact size
# 0.025 and delta=0.20. Therefore, you would need to have downloaded
# LIB.a025.d20 using fetch(0.015,0.20). The example below instead uses
# the toy data that comes with the package. The baseline probability is
# assumed to be between 0.3 and 0.5.
rdata_file = system.file('files', 'LIB.a025.d20.Rdata', package = 'exact.n')
load(rdata_file)
#' main.function(.025,0.20,p0=c(0.3,0.5),beta=0.75,plt=TRUE)
# The value of the function is the minimum value of n1 for a range
# of values of n0. The sample size ratio is limited to 5 by default.
```

n1.get

*Find smallest value of n1 that achieves target power*

## Description

Function calculates minimum value of n1 that achieves power beta. If there is no solution less than 500, it models observed powers as a function of n1 and then extrapolates. It returns an infinite value if the power is unattainable.

## Usage

```
n1.get(data, n0, beta, delta, alpha, type = 1, plt = FALSE)
```

## Arguments

data	a matrix with column names beta, p0.vals, n0, n1 and 481^2 rows (See details)
n0	scalar value of n0 between 20 and 500 inclusive
beta	scalar target for power
delta	value of clinically relevant difference
alpha	value of nominal size of test
type	type of minimum solution (See details)
plt	if true produce diagnostic plots

## Details

This function is called by n1.get.vector and will likely never be run by the user.

The data matrix will be a subset of one of the 85 main databases. Supplying alpha and delta loads the appropriate database and selecting a value of p0 further subsets this data base. The resulting matrix will have 4 columns and 481^2 rows corresponding to all values of n0 and n1 from 20 to 500 inclusive and is suitable for input into n1.get.

If type=1, the smallest value N1 of n1 so that power > beta is returned. If type=2, the smallest value N1 of n1 so that power > beta for all n1>=N1 is returned.

## Value

a single scalar value of n1. An integer indicates a solution was found in the database. A non-integer indicates an extrapolated solution. An Inf value indicates no extrapolated solution was found.

## Author(s)

Chris J. Lloyd

## References

C.J. Lloyd (2022) Exact samples sizes for clinical trials subject to size and power constraints. Preprint. [doi:10.13140/RG.2.2.11828.94085](https://doi.org/10.13140/RG.2.2.11828.94085)

## Examples

```
# Load toy version of power library for alpha=0.025, delta=0.20.
# Alternatively, load the full library using fetch.data(alpha=0.025,delta=0.20)
rdata_file = system.file('files', 'LIB.a025.d20.Rdata', package = 'exact.n')
load(rdata_file)
data=LIB.a025.d20[LIB.a025.d20[,2]==0.5,] # select subset with p0=.5
# For given value of n0, what minimum value of n1 ensures power at least 0.7?
n1.get(data, n0=70, beta=.7, delta=.2, alpha=0.025,
       type = 1, plt = TRUE) # Explicit solution 63 found in data base
n1.get(data, n0=50, beta=.7, delta=.2, alpha=0.025,
       type = 1, plt = TRUE) # Approximate solution 131 extrapolated from toy data base
# You can check the accuracy of this extrapolated result:
# POWER(n0=50,n1=131,alpha=0.025,delta=0.2,p0=0.5,type="elr")
```

```
# The minimum power at p0=0.5 is 0.699, slightly less than 0.7.
# With the full library n1.get returns the correct answer of n1=136.
n1.get(data, n0=30, beta=.7, delta=.2, alpha=0.025,
       type = 1, plt = TRUE) # Extrapolated solution is infinite
```

**n1.get.solution***Find minimal n1 achieving target power for range of values of p0***Description**

This function calls n1.get.vector, runs if for all values of p0 within the supplied range and then takes the worst (i.e. largest) solution for n1

**Usage**

```
n1.get.solution(data, beta, p0, delta, alpha, type = 1)
```

**Arguments**

data	power database for selected value of alpha and delta
beta	scalar target for power
p0	single value or range of values for baseline probability
delta	value of clinically relevant difference
alpha	value of nominal size of test
type	type of minimum solution (See details)

**Value**

vector of solutions for n1 with name vector equal to range of n0 values

**Author(s)**

Chris J. Lloyd

## Examples

```
# Load toy version of power library for alpha=0.025, delta=0.20.
rdata_file = system.file('files', 'LIB.a025.d20.Rdata', package = 'exact.n')
load(rdata_file)
# n0 solutions when p0=0.5
n1.get.solution(LIB.a025.d20,beta=.7,p0=0.5,delta=0.2,alpha=0.025,type=1)
# n0 solutions for p0 between 0.4 ad 0.5
n1.get.solution(LIB.a025.d20,beta=.7,p0=c(0.4,0.5),delta=0.2,alpha=0.025,type=1)
```

POWER

*Exact Power of Test for Selected Sample Sizes.*

## Description

For known values of the sizes  $n_0$ , this function computes the exact probability of rejecting the null as a function of baseline probability.

## Usage

```
POWER(
  n0,
  n1,
  alpha = 0.05,
  delta = 0,
  psi = 0,
  type = "lr",
  sided = 1,
  p0 = NULL,
  obj = NULL
)
```

## Arguments

<code>n0</code>	control sample size
<code>n1</code>	treatment sample size
<code>alpha</code>	value of nominal size of test
<code>delta</code>	value of clinically relevant difference
<code>psi</code>	null value of risk difference $p_1 - p_0$
<code>type</code>	either "lr" for approximate or "elr" for quasi-exact test
<code>sided</code>	(1 or 2 sided test)
<code>p0</code>	baseline probability. If missing, a grid of values is created for plotting. A scalar value can also be supplied.

**obj** Optional object with all possible p-values. Must be a list with elements y0, y1, P (typically output of lr.rd or ESTEP.rd). If not supplied then object is generated from n0, n1 and psi.

## Details

p0 values must be between max(0,-delta) and min(1,1-delta)

## Value

list with element x (containing values of baseline probability) and element y (containing corresponding exact powers)

suppressWarnings(graphics::par(oldpar))

```

**power.image***Image plot of power*

## Description

Creates image plot of exact power for range of values of n0 and n1. Optionally, the image plot will show where power exceeds a provided power target.

## Usage

```
power.image(data, p = 0.2, binary = TRUE, beta = 0.75)
```

## Arguments

<b>data</b>	a matrix of powers with columns named beta p0.vals, n0 and n1.
<b>p</b>	a scalar value for p0.vals that is used to select the subset of data.
<b>binary</b>	If TRUE only the binary indicator of power exceeding beta is displayed.
<b>beta</b>	target value of power

## Details

data will be one of the 85 saved objects corresponding to a selected value of alpha and delta.

**Value**

No return value and if the 'binary' parameter is TRUE then an image will be displayed

**Author(s)**

Chris J. Lloyd

**Examples**

```
oldpar <- graphics::par()
# Load toy version of power library for alpha=0.025, delta=0.20.
rdata_file = system.file('files', 'LIB.a025.d20.Rdata', package = 'exact.n')
load(rdata_file)
graphics::par(mfrow=c(1,2))
power.image(LIB.a025.d20,p=.5,binary=FALSE)
power.image(LIB.a025.d20,p=.2,beta=.7,binary=TRUE)
suppressWarnings(graphics::par(oldpar))
```
