mcclust-package Process MCMC Sample of Clusterings.

Description

Implements methods for processing a sample of (hard) clusterings, e.g. the MCMC output of a Bayesian clustering model. Among them are methods that find a single best clustering to represent the sample, which are based on the posterior similarity matrix or a relabelling algorithm.

Details

Package:	mcclust
Type:	Package
Version:	1.0
Date:	2009-03-12
License:	GPL (>= 2)
LazyLoad:	yes

Most important functions:

comp.psm for computing posterior similarity matrix (PSM). Based on the PSM maxpear and minbinder provide several optimization methods to find a clustering with maximal posterior expected adjusted Rand index with the true clustering or one that minimizes the posterior expectation of a loss function by Binder (1978). minbinder provides the optimization algorithm of Lau and Green.

relabel contains the relabelling algorithm of Stephens (2000).

arandi and vi.dist compute distance functions for clusterings, the (adjusted) Rand index and the entropy-based variation of information distance.

Examples

```
data(cls.draw2)
# sample of 500 clusterings from a Bayesian cluster model
tru.class <- rep(1:8,each=50)</pre>
# the true grouping of the observations
psm2 <- comp.psm(cls.draw2)</pre>
# posterior similarity matrix
# optimize criteria based on PSM
mbind2 <- minbinder(psm2)</pre>
mpear2 <- maxpear(psm2)</pre>
# Relabelling
k <- apply(cls.draw2,1, function(cl) length(table(cl)))</pre>
max.k <- as.numeric(names(table(k))[which.max(table(k))])</pre>
relab2 <- relabel(cls.draw2[k==max.k,])</pre>
# compare clusterings found by different methods with true grouping
arandi(mpear2$cl, tru.class)
arandi(mbind2$cl, tru.class)
```

arandi

(Adjusted) Rand Index for Clusterings

Description

Computes the adjusted or unadjusted Rand index between two clusterings/partitions of the same objects.

Usage

arandi(cl1, cl2, adjust = TRUE)

arandi(relab2\$cl, tru.class)

Arguments

cl1,cl2	vectors of cluster memberships (need to have the same lengths).
adjust	logical. Should index be adjusted? Defaults to TRUE.

Details

The Rand index is based on how often the two clusterings agree in the treatment of pairs of observations, where agreement means that two observations are in/not in the same cluster in both clusterings.

The adjusted Rand index adjusts for the expected number of chance agreements.

Formulas of Hubert and Arabie (1985) are used for the computation.

vi.dist

Examples

```
cl1 <- sample(1:3,10,replace=TRUE)
cl2 <- c(cl1[1:5], sample(1:3,5,replace=TRUE))
arandi(cl1,cl2)
arandi(cl1,cl2,adjust=FALSE)
```

cls.draw1.5	Sample of Clusterings from Posterior Distribution of Bayesian Cluster
	Model

Description

Output of a Dirichlet process mixture model with normal components fitted to the data set Ysim1.5. True clusters are given by rep(1:8, each =50).

Usage

```
data(cls.draw1.5)
```

Format

matrix with 500 rows and 400 columns. Each row contains a clustering of the 400 observations.

Source

Fritsch, A. and Ickstadt, K. (2009) An improved criterion for clustering based on the posterior similarity matrix, *Bayesian Analysis*, accepted.

cls.draw2

Description

Output of a Dirichlet process mixture model with normal components fitted to the data set Ysim2. True clusters are given by rep(1:8, each =50).

Usage

```
data(cls.draw2)
```

Format

matrix with 500 rows and 400 columns. Each row contains a clustering of the 400 observations.

Source

Fritsch, A. and Ickstadt, K. (2009) An improved criterion for clustering based on the posterior similarity matrix, *Bayesian Analysis*, accepted.

cltoSim

Compute Similarity Matrix for a Clustering and vice versa

Description

A similarity matrix is a symmetric matrix whose entry [i, j] is 1 if observation i and j are in the same cluster and 0 otherwise.

Usage

cltoSim(cl)
Simtocl(Sim)

Arguments

cl	vector of cluster memberships
Sim	similarity matrix

Warning

Simtocl does **not** check whether Sim is a valid similarity matrix, e.g. that Sim[i,j]==1 if Sim[i,k]==1 and Sim[j,k]==1.

Author(s)

Arno Fritsch, <arno.fritsch@tu-dortmund.de>

See Also

comp.psm for an average similarity matrix.

Examples

```
cl <- c(3,3,1,2,2)
(Sim <- cltoSim(cl))
Simtocl(Sim)
# not a valid similarity matrix
(Sim2 <- matrix(c(1,0,1,0,1,1,1,1,1), ncol=3))
Simtocl(Sim2) # no warning</pre>
```

comp.psm

Estimate Posterior Similarity Matrix

Description

For a sample of clusterings of the same objects the proportion of clusterings in which observation i and j are together in a cluster is computed and a matrix containing all proportions is given out.

Usage

```
comp.psm(cls)
```

Arguments

cls

a matrix in which every row corresponds to a clustering of the ncol(cls) objects

Details

In Bayesian cluster analysis the posterior similarity matrix is a matrix whose entry [i, j] contains the posterior probability that observation i and j are together in a cluster. It is estimated by the proportion of a posteriori clusterings in which i and j cluster together.

Value

a symmetric ncol(cls)*ncol(cls) matrix

Author(s)

Arno Fritsch, <arno.fritsch@tu-dortmund.de>

maxpear

See Also

cltoSim

Examples

```
(cls <- rbind(c(1,1,2,2),c(1,1,2,2),c(1,2,2,2),c(2,2,1,1)))
comp.psm(cls)</pre>
```

maxpear

Maximize/Compute Posterior Expected Adjusted Rand Index

Description

Based on a posterior similarity matrix of a sample of clusterings maxpear finds the clustering that maximizes the posterior expected Rand adjusted index (PEAR) with the true clustering, while pear computes PEAR for several provided clusterings.

Usage

pear(cls,psm)

Arguments

psm	a posterior similarity matrix, usually obtained from a call to comp.psm.
cls, cls.draw	a matrix in which every row corresponds to a clustering of the ncol(cls) objects. cls.draw refers to the clusterings that have been used to compute psm, cls.draw has to be provided if method="draw" or "all".
method	the maximization method used. Should be one of "avg", "comp", "draws" or "all". The default is "avg".
max.k	integer, if method="avg" or "comp" the maximum number of clusters up to which the hierarchical clustering is cut. Defaults to ceiling(nrow(psm)/8).

Details

For method="avg" and "comp" 1-psm is used as a distance matrix for hierarchical clustering with average/complete linkage. The hierarchical clustering is cut for the cluster sizes 1:max.k and PEAR computed for these clusterings.

Method "draws" simply computes PEAR for each row of cls.draw and takes the maximum. If method="all" all maximization methods are applied.

Value

cl	clustering with maximal value of PEAR. If method="all" a matrix containing the clustering with the higest value of PEAR over all methods in the first row and the clusterings of the individual methods in the next rows.
value	value of PEAR. A vector corresponding to the rows of cl if method="all".
method	the maximization method used.

Author(s)

Examples

```
data(cls.draw1.5)
# sample of 500 clusterings from a Bayesian cluster model
tru.class <- rep(1:8,each=50)
# the true grouping of the observations
psm1.5 <- comp.psm(cls.draw1.5)
mpear1.5 <- maxpear(psm1.5)
table(mpear1.5$cl, tru.class)
# Does hierachical clustering with Ward's method lead
# to a better value of PEAR?
hclust.ward <- hclust(as.dist(1-psm1.5), method="ward")
cls.ward <- t(apply(matrix(1:20),1, function(k) cutree(hclust.ward,k=k)))
ward1.5 <- pear(cls.ward, psm1.5)</pre>
```

max(ward1.5) > mpear1.5\$value

medv

Clustering Method of Medvedovic

Description

Based on a posterior similarity matrix of a sample of clusterings medv obtains a clustering by using 1-psm as distance matrix for hierarchical clustering with complete linkage. The dendrogram is cut at a value h close to 1.

minbinder

Usage

medv(psm, h=0.99)

Arguments

psm	a posterior similarity matrix, usually obtained from a call to comp.psm.
h	The height at which the dendrogram is cut.

Value

vector of cluster memberships.

Author(s)

Arno Fritsch, <arno.fritsch@tu-dortmund.de>

References

Medvedovic, M. Yeung, K. and Bumgarner, R. (2004) Bayesian mixture model based clustering of replicated microarray data, *Bioinformatics*, **20**, 1222-1232.

See Also

comp.psm for computing posterior similarity matrix, maxpear, minbinder, relabel for other possibilities for processing a sample of clusterings.

Examples

```
data(cls.draw1.5)
# sample of 500 clusterings from a Bayesian cluster model
tru.class <- rep(1:8,each=50)
# the true grouping of the observations
psm1.5 <- comp.psm(cls.draw1.5)
medv1.5 <- medv(psm1.5)
table(medv1.5, tru.class)</pre>
```

minbinder

Minimize/Compute Posterior Expectation of Binders Loss Function

Description

Based on a posterior similarity matrix of a sample of clusterings minbinder finds the clustering that minimizes the posterior expectation of Binders loss function, while binder computes the posterior expected loss for several provided clusterings.

Usage

```
binder(cls,psm)
```

laugreen(psm, start.cl, tol=0.001)

Arguments

psm	a posterior similarity matrix, usually obtained from a call to comp.psm.
cls, cls.draw	a matrix in which every row corresponds to a clustering of the ncol(cls) objects. cls.draw refers to the clusterings that have been used to compute psm, cls.draw has to be provided if method="draw" or "all".
method	the maximization method used. Should be one of "avg", "comp", "draws", "laugreen" or "all". The default is "avg".
max.k	integer, if method="avg" or "comp" the maximum number of clusters up to which the hierarchical clustering is cut. Defaults to ceiling(nrow(psm)/4).
include.lg	logical, should method "laugreen" be included when method="all"? Defaults to FALSE.
start.cl	<pre>clustering used as starting point for method="laugreen". If NULL start.cl= 1:nrow(psm) is used.</pre>
tol	convergence tolerance for method="laugreen".

Details

The posterior expected loss is the sum of the absolute differences of the indicator function of observation i and j clustering together and the posterior probability that they are in one cluster.

For method="avg" and "comp" 1-psm is used as a distance matrix for hierarchical clustering with average/complete linkage. The hierachical clustering is cut for the cluster sizes 1:max.k and the posterior expected loss is computed for these clusterings.

Method "draws" simply computes the posterior expected loss for each row of cls.draw and takes the minimum.

Method "laugreen" implements the algorithm of Lau and Green (2007), which is based on binary integer programming. Since the method can take some time to converge it is only used if explicitly demanded with method="laugreen" or method="all" *and* include.lg=TRUE. If method="all" all minimization methods except "laugreen" are applied.

Value

cl	clustering with minimal value of expected loss. If method="all" a matrix con- taining the clustering with the smallest value of the expected loss over all meth- ods in the first row and the clusterings of the individual methods in the next rows.
value	value of posterior expected loss. A vector corresponding to the rows of cl if method="all".

minbinder

method	the maximization method used.
iter.lg	if method="laugreen" the number of iterations the method needed to converge.

mbind.lg\$value

norm.label

Description

Cluster labels of a clusterings are replaced by 1:length(table(cl)).

Usage

```
norm.label(cl)
```

Arguments cl

vector of cluster memberships

Value

the clustering with normed labels.

Author(s)

Arno Fritsch, <arno.fritsch@tu-dortmund.de>

See Also

relabel for labelling a sample of clusterings the same way

Examples

```
(cl <- sample(c(13,12,34), 13, replace=TRUE))
norm.label(cl)
(cl <- sample(c("a","b","f31"), 13, replace=TRUE))
norm.label(cl)</pre>
```

relabel

Stephens' Relabelling Algorithm for Clusterings

Description

For a sample of clusterings in which corresponding clusters have different labels the algorithm attempts to bring the clusterings to a unique labelling.

Usage

relabel(cls, print.loss = TRUE)

relabel

Arguments

cls	a matrix in which every row corresponds to a clustering of the ncol(cls) objects.
print.loss	logical, should current value of loss function be printed after each iteration? Defaults to TRUE.

Details

The algorithm minimizes the loss function

$$\sum_{m=1}^{M} \sum_{i=1}^{n} \sum_{j=1}^{K} -\log \hat{p}_{ij} \cdot I_{\{z_i^{(m)}=j\}}$$

over the M clusterings, n observations and K clusters, where \hat{p}_{ij} is the estimated probability that observation i belongs to cluster j and $z_i^{(m)}$ indicates to which cluster observation i belongs in clustering m. $I_{\{.\}}$ is an indicator function.

Minimization is achieved by iterating the estimation of \hat{p}_{ij} over all clusterings and the minimization of the loss function in each clustering by permuting the cluster labels. The latter is done by linear programming.

Value

cls	the input cls with unified labelling.
Ρ	an $n \times K$ matrix, where entry $[i, j]$ contains the estimated probability that observation i belongs to cluster j .
loss.val	value of the loss function.
cl	vector of cluster memberships that have the highest probabilities \hat{p}_{ij} .

Warning

The algorithm assumes that the number of clusters K is fixed. If this is not the case K is taken to be the most common number of clusters. Clusterings with other numbers of clusters are discarded and a warning is issued.

Note

The implementation is a variant of the algorithm of Stephens which is originally applied to draws of parameters for each observation, not to cluster labels.

vi.dist

Variation of Information Distance for Clusterings

Description

Computes the 'variation of information' distance of Meila (2007) between two clusterings/partitions of the same objects.

Usage

vi.dist(cl1, cl2, parts = FALSE, base = 2)

Arguments

cl1,cl2	vectors of cluster memberships (need to have the same lengths).
parts	logical; should the two conditional entropies also be returned?
base	base of logarithm used for computation of entropy and mutual information.

Details

The variation of information distance is the sum of the two conditional entropies of one clustering given the other. For details see Meila (2007).

Value

The VI distance. If parts=TRUE the two conditional entropies are appended.
