

Package ‘reservr’

June 24, 2024

Title Fit Distributions and Neural Networks to Censored and Truncated Data

Version 0.0.3

Description Define distribution families and fit them to interval-censored and interval-truncated data, where the truncation bounds may depend on the individual observation. The defined distributions feature density, probability, sampling and fitting methods as well as efficient implementations of the log-density $\log f(x)$ and log-probability $\log P(x_0 \leq X \leq x_1)$ for use in 'TensorFlow' neural networks via the 'tensorflow' package. Allows training parametric neural networks on interval-censored and interval-truncated data with flexible parameterization. Applications include Claims Development in Non-Life Insurance, e.g. modelling reporting delay distributions from incomplete data, see Bücher, Rosenstock (2022) [<doi:10.1007/s13385-022-00314-4>](https://doi.org/10.1007/s13385-022-00314-4).

<i>as_params</i>	<i>Convert TensorFlow tensors to distribution parameters recursively</i>
------------------	--

Description

Convert TensorFlow tensors to distribution parameters recursively

Usage

```
as_params(x)
```

Arguments

<code>x</code>	possibly nested list structure of tensorflow.tensors
----------------	--

Value

A nested list of vectors suitable as distribution parameters

Examples

```
if (interactive()) {
  tf_params <- list(
    probs = k_matrix(t(c(0.5, 0.3, 0.2))),
    shapes = k_matrix(t(c(1L, 2L, 3L)), dtype = "int32"),
    scale = keras3::as_tensor(1.0, keras3::config_floatx())
  )
  params <- as_params(tf_params)
  dist <- dist_erlangmix(vector("list", 3L))
  dist$sample(10L, with_params = params)
}
```

<code>blended_transition</code>	<i>Transition functions for blended distributions</i>
---------------------------------	---

Description

Transition functions for blended distributions

Usage

```
blended_transition(x, u, eps, .gradient = FALSE, .extend_na = FALSE)
```

```
blended_transition_inv(x, u, eps, .component)
```

Arguments

<code>x</code>	Points to evaluate at
<code>u</code>	Sorted vector of blending thresholds, or rowwise sorted matrix of blending thresholds
<code>eps</code>	Corresponding vector or matrix of blending bandwidths. Must be positive and the same dimensions as <code>u</code> , or scalar. No rowwise blending regions ($u - \text{eps}$, $u + \text{eps}$) may overlap.
<code>.gradient</code>	Also evaluate the gradient with respect to <code>x</code> ?

.extend_na	Extend out-of range transitions by the last in-range value (i.e. the corresponding u) or by NA?
.component	Component index (up to <code>length(u) + 1</code>) to invert.

Value

`blended_transition` returns a matrix with `length(x)` rows and `length(u) + 1` columns containing the transformed values for each of the blending components. If `.gradient` is TRUE, an attribute "gradient" is attached with the same dimensions, containing the derivative of the respective transition component with respect to `x`.

`blended_transition_inv` returns a vector with `length(x)` values containing the inverse of the transformed values for the `.component`th blending component.

Examples

```
library(ggplot2)
xx <- seq(from = 0, to = 20, length.out = 101)
blend_mat <- blended_transition(xx, u = 10, eps = 3, .gradient = TRUE)
ggplot(
  data.frame(
    x = rep(xx, 2L),
    fun = rep(c("p", "q"), each = length(xx)),
    y = as.numeric(blend_mat),
    relevant = c(xx <= 13, xx >= 7)
  ),
  aes(x = x, y = y, color = fun, linetype = relevant)
) %+%
  geom_line() %+%
  theme_bw() %+%
  theme(
    legend.position = "bottom", legend.box = "horizontal"
  ) %+%
  guides(color = guide_legend(direction = "horizontal", title = ""),
         linetype = guide_none()) %+%
  scale_linetype_manual(values = c("TRUE" = 1, "FALSE" = 3))

ggplot(
  data.frame(
    x = rep(xx, 2L),
    fun = rep(c("p'", "q'"), each = length(xx)),
    y = as.numeric(attr(blend_mat, "gradient")),
    relevant = c(xx <= 13, xx >= 7)
  ),
  aes(x = x, y = y, color = fun, linetype = relevant)
) %+%
  geom_line() %+%
  theme_bw() %+%
  theme(
    legend.position = "bottom", legend.box = "horizontal"
  ) %+%
  guides(color = guide_legend(direction = "horizontal", title = ""),
         linetype = guide_none()) %+%
  scale_linetype_manual(values = c("TRUE" = 1, "FALSE" = 3))
```

`callback_adaptive_lr` *Keras Callback for adaptive learning rate with weight restoration*

Description

Provides a keras callback similar to [keras3::callback_reduce_lr_on_plateau\(\)](#) but which also restores the weights to the best seen so far whenever a learning rate reduction occurs, and with slightly more restrictive improvement detection.

Usage

```
callback_adaptive_lr(
  monitor = "val_loss",
  factor = 0.1,
  patience = 10L,
  verbose = 0L,
  mode = c("auto", "min", "max"),
  delta_abs = 1e-04,
  delta_rel = 0,
  cooldown = 0L,
  min_lr = 0,
  restore_weights = TRUE
)
```

Arguments

<code>monitor</code>	quantity to be monitored.
<code>factor</code>	factor by which the learning rate will be reduced. <code>new_lr = old_lr * factor</code> .
<code>patience</code>	number of epochs with no significant improvement after which the learning rate will be reduced.
<code>verbose</code>	integer. Set to 1 to receive update messages.
<code>mode</code>	Optimisation mode. "auto" detects the mode from the name of <code>monitor</code> . "min" monitors for decreasing metrics. "max" monitors for increasing metrics.
<code>delta_abs</code>	Minimum absolute metric improvement per epoch. The learning rate will be reduced if the average improvement is less than <code>delta_abs</code> per epoch for <code>patience</code> epochs.
<code>delta_rel</code>	Minimum relative metric improvement per epoch. The learning rate will be reduced if the average improvement is less than $ metric * \text{delta_rel}$ per epoch for <code>patience</code> epochs.
<code>cooldown</code>	number of epochs to wait before resuming normal operation after learning rate has been reduced. The minimum number of epochs between two learning rate reductions is <code>patience + cooldown</code> .
<code>min_lr</code>	lower bound for the learning rate. If a learning rate reduction would lower the learning rate below <code>min_lr</code> , it will be clipped at <code>min_lr</code> instead and no further reductions will be performed.

restore_weights

Bool. If TRUE, the best weights will be restored at each learning rate reduction.
This is very useful if the metric oscillates.

Details

Note that while `keras3::callback_reduce_lr_on_plateau()` automatically logs the learning rate as a metric 'lr', this is currently impossible from R. Thus, if you want to also log the learning rate, you should add `keras3::callback_reduce_lr_on_plateau()` with a high `min_lr` to effectively disable the callback but still monitor the learning rate.

Value

A KerasCallback suitable for passing to `keras3::fit()`.

Examples

```
dist <- dist_exponential()
group <- sample(c(0, 1), size = 100, replace = TRUE)
x <- dist$sample(100, with_params = list(rate = group + 1))
global_fit <- fit(dist, x)

if (interactive()) {
  library(keras3)
  l_in <- layer_input(shape = 1L)
  mod <- tf_compile_model(
    inputs = list(l_in),
    intermediate_output = l_in,
    dist = dist,
    optimizer = optimizer_adam(),
    censoring = FALSE,
    truncation = FALSE
  )
  tf_initialise_model(mod, global_fit$params)
  fit_history <- fit(
    mod,
    x = as_tensor(group, config_floatx()),
    y = as_trunc_obs(x),
    epochs = 20L,
    callbacks = list(
      callback_adaptive_lr("loss", factor = 0.5, patience = 2L, verbose = 1L, min_lr = 1.0e-4),
      callback_reduce_lr_on_plateau("loss", min_lr = 1.0) # to track lr
    )
  )
  plot(fit_history)

  predicted_means <- predict(mod, data = as_tensor(c(0, 1), config_floatx()))
}
```

callback_debug_dist_gradients*Callback to monitor likelihood gradient components*

Description

Provides a keras callback to monitor the individual components of the censored and truncated likelihood. Useful for debugging TensorFlow implementations of Distributions.

Usage

```
callback_debug_dist_gradients(
    object,
    data,
    obs,
    keep_grads = FALSE,
    stop_on_na = TRUE,
    verbose = TRUE
)
```

Arguments

object	A resrvr_keras_model created by tf_compile_model() .
data	Input data for the model.
obs	Observations associated to data.
keep_grads	Log actual gradients? (memory hungry!)
stop_on_na	Stop if any likelihood component as NaN in its gradients?
verbose	Print a message if training is halted? The Message will contain information about which likelihood components have NaN in their gradients.

Value

A KerasCallback suitable for passing to [keras3::fit\(\)](#).

Examples

```
dist <- dist_exponential()
group <- sample(c(0, 1), size = 100, replace = TRUE)
x <- dist$sample(100, with_params = list(rate = group + 1))
global_fit <- fit(dist, x)

if (interactive()) {
  library(keras3)
  l_in <- layer_input(shape = 1L)
  mod <- tf_compile_model(
    inputs = list(l_in),
    intermediate_output = l_in,
```

```

    dist = dist,
    optimizer = optimizer_adam(),
    censoring = FALSE,
    truncation = FALSE
)
tf_initialise_model(mod, global_fit$params)
gradient_tracker <- callback_debug_dist_gradients(
  mod,
  as_tensor(group, config_floatx()),
  x,
  keep_grads = TRUE
)
fit_history <- fit(
  mod,
  x = as_tensor(group, config_floatx()),
  y = x,
  epochs = 20L,
  callbacks = list(
    callback_adaptive_lr("loss", factor = 0.5, patience = 2L, verbose = 1L, min_lr = 1.0e-4),
    gradient_tracker,
    callback_reduce_lr_on_plateau("loss", min_lr = 1.0) # to track lr
  )
)
gradient_tracker$gradient_logs[[20]]$dens

plot(fit_history)

predicted_means <- predict(mod, data = as_tensor(c(0, 1), config_floatx()))
}

```

Distribution*Base class for Distributions***Description**

Represents a modifiable Distribution family

Active bindings

`default_params` Get or set (non-recursive) default parameters of a Distribution

`param_bounds` Get or set (non-recursive) parameter bounds (box constraints) of a Distribution

Methods**Public methods:**

- `Distribution$new()`
- `Distribution$sample()`
- `Distribution$density()`

- `Distribution$tf_logdensity()`
- `Distribution$probability()`
- `Distribution$tf_logprobability()`
- `Distribution$quantile()`
- `Distribution$hazard()`
- `Distribution$diff_density()`
- `Distribution$diff_probability()`
- `Distribution$is_in_support()`
- `Distribution$is_discrete_at()`
- `Distribution$tf_is_discrete_at()`
- `Distribution$has_capability()`
- `Distribution$get_type()`
- `Distribution$get_components()`
- `Distribution$is_discrete()`
- `Distribution$is_continuous()`
- `Distribution$require_capability()`
- `Distribution$get_dof()`
- `Distribution$get_placeholders()`
- `Distribution$get_params()`
- `Distribution$tf_make_constants()`
- `Distribution$tf_compile_params()`
- `Distribution$get_param_bounds()`
- `Distribution$get_param_constraints()`
- `Distribution$export_functions()`
- `Distribution$clone()`

Method new():

Usage:

```
Distribution$new(type, caps, params, name, default_params)
```

Arguments:

`type` Type of distribution. This is a string constant for the default implementation. Distributions with non-constant type must override the `get_type()` function.

`caps` Character vector of capabilities to fuel the default implementations of `has_capability()` and `require_capability()`. Distributions with dynamic capabilities must override the `has_capability()` function.

`params` Initial parameter bounds structure, backing the `param_bounds` active binding (usually a list of intervals).

`name` Name of the Distribution class. Should be CamelCase and end with "Distribution".

`default_params` Initial fixed parameters backing the `default_params` active binding (usually a list of numeric / NULLs).

Details: Construct a Distribution instance

Used internally by the `dist_*` functions.

Method sample():*Usage:*`Distribution$sample(n, with_params = list())`*Arguments:*`n` number of samples to draw.`with_params` Distribution parameters to use. Each parameter value can also be a numeric vector of length `n`. In that case the `i`-th sample will use the `i`-th parameters.*Details:* Sample from a Distribution*Returns:* A length `n` vector of i.i.d. random samples from the Distribution with the specified parameters.*Examples:*`dist_exponential(rate = 2.0)$sample(10)`**Method** density():*Usage:*`Distribution$density(x, log = FALSE, with_params = list())`*Arguments:*`x` Vector of points to evaluate the density at.`log` Flag. If TRUE, return the log-density instead.`with_params` Distribution parameters to use. Each parameter value can also be a numeric vector of length `length(x)`. In that case, the `i`-th density point will use the `i`-th parameters.*Details:* Density of a Distribution*Returns:* A numeric vector of (log-)densities*Examples:*`dist_exponential()$density(c(1.0, 2.0), with_params = list(rate = 2.0))`**Method** tf_logdensity():*Usage:*`Distribution$tf_logdensity()`*Details:* Compile a TensorFlow function for log-density evaluation*Returns:* A `tf_function` taking arguments `x` and `args` returning the log-density of the Distribution evaluated at `x` with parameters `args`.**Method** probability():*Usage:*

```
Distribution$probability(
  q,
  lower.tail = TRUE,
  log.p = FALSE,
  with_params = list()
)
```

Arguments:

`q` Vector of points to evaluate the probability function at.
`lower.tail` If TRUE, return $P(X \leq q)$. Otherwise return $P(X > q)$.
`log.p` If TRUE, probabilities are returned as $\log(p)$.
`with_params` Distribution parameters to use. Each parameter value can also be a numeric vector of length `length(q)`. In that case, the i -th probability point will use the i -th parameters.

Details: Cumulative probability of a Distribution

Returns: A numeric vector of (log-)probabilities

Examples:

```
dist_exponential()$probability(
  c(1.0, 2.0),
  with_params = list(rate = 2.0)
)
```

Method tf_logprobability():

Usage:

```
Distribution$tf_logprobability()
```

Details: Compile a TensorFlow function for log-probability evaluation

Returns: A `tf_function` taking arguments `qmin`, `qmax` and `args` returning the log-probability of the Distribution evaluated over the closed interval $[qmin, qmax]$ with parameters `args`.

Method quantile():

Usage:

```
Distribution$quantile(
  p,
  lower.tail = TRUE,
  log.p = FALSE,
  with_params = list()
)
```

Arguments:

`p` Vector of probabilities.

`lower.tail` If TRUE, return $P(X \leq q)$. Otherwise return $P(X > q)$.

`log.p` If TRUE, probabilities are returned as $\log(p)$.

`with_params` Distribution parameters to use. Each parameter value can also be a numeric vector of length `length(p)`. In that case, the i -th quantile will use the i -th parameters.

Details: Quantile function of a Distribution

Returns: A numeric vector of quantiles

Examples:

```
dist_exponential()$quantile(c(0.1, 0.5), with_params = list(rate = 2.0))
```

Method hazard():

Usage:

```
Distribution$hazard(x, log = FALSE, with_params = list())
```

Arguments:

- x Vector of points.
- log Flag. If TRUE, return the log-hazard instead.
- with_params Distribution parameters to use. Each parameter value can also be a numeric vector of length `length(x)`. In that case, the i-th hazard point will use the i-th parameters.

Details: Hazard function of a Distribution

Returns: A numeric vector of (log-)hazards

Examples:

```
dist_exponential(rate = 2.0)$hazard(c(1.0, 2.0))
```

Method `diff_density()`:

Usage:

```
Distribution$diff_density(x, log = FALSE, with_params = list())
```

Arguments:

- x Vector of points.
- log Flag. If TRUE, return the gradient of the log-density instead.
- with_params Distribution parameters to use. Each parameter value can also be a numeric vector of length `length(x)`. In that case, the i-th density point will use the i-th parameters.

Details: Gradients of the density of a Distribution

Returns: A list structure containing the (log-)density gradients of all free parameters of the Distribution evaluated at x.

Examples:

```
dist_exponential()$diff_density(
  c(1.0, 2.0),
  with_params = list(rate = 2.0)
)
```

Method `diff_probability()`:

Usage:

```
Distribution$diff_probability(
  q,
  lower.tail = TRUE,
  log.p = FALSE,
  with_params = list()
)
```

Arguments:

- q Vector of points to evaluate the probability function at.
- lower.tail If TRUE, return $P(X \leq q)$. Otherwise return $P(X > q)$.
- log.p If TRUE, probabilities are returned as $\log(p)$.
- with_params Distribution parameters to use. Each parameter value can also be a numeric vector of length `length(q)`. In that case, the i-th probability point will use the i-th parameters.

Details: Gradients of the cumulative probability of a Distribution

Returns: A list structure containing the cumulative (log-)probability gradients of all free parameters of the Distribution evaluated at q.

Examples:

```
dist_exponential()$diff_probability(
  c(1.0, 2.0),
  with_params = list(rate = 2.0)
)
```

Method `is_in_support()`:

Usage:

```
Distribution$is_in_support(x, with_params = list())
```

Arguments:

x Vector of points

with_params Distribution parameters to use. Each parameter value can also be a numeric vector of length `length(x)`. In that case, the i-th point will use the i-th parameters.

Details: Determine if a value is in the support of a Distribution

Returns: A logical vector with the same length as x indicating whether x is part of the support of the distribution given its parameters.

Examples:

```
dist_exponential(rate = 1.0)$is_in_support(c(-1.0, 0.0, 1.0))
```

Method `is_discrete_at()`:

Usage:

```
Distribution$is_discrete_at(x, with_params = list())
```

Arguments:

x Vector of points

with_params Distribution parameters to use. Each parameter value can also be a numeric vector of length `length(x)`. In that case, the i-th point will use the i-th parameters.

Details: Determine if a value has positive probability

Returns: A logical vector with the same length as x indicating whether there is a positive probability mass at x given the Distribution parameters.

Examples:

```
dist_dirac(point = 0.0)$is_discrete_at(c(0.0, 1.0))
```

Method `tf_is_discrete_at()`:

Usage:

```
Distribution$tf_is_discrete_at()
```

Details: Compile a TensorFlow function for discrete support checking

Returns: A `tf_function` taking arguments x and args returning whether the Distribution has a point mass at x given parameters args.

Method `has_capability()`:

Usage:

```
Distribution$has_capability(caps)
```

Arguments:

caps Character vector of capabilities

Details: Check if a capability is present

Returns: A logical vector the same length as caps.

Examples:

```
dist_exponential()$has_capability("density")
```

Method get_type():

Usage:

```
Distribution$get_type()
```

Details: Get the type of a Distribution. Type can be one of discrete, continuous or mixed.

Returns: A string representing the type of the Distribution.

Examples:

```
dist_exponential()$get_type()
dist_dirac()$get_type()
```

```
dist_mixture(list(dist_dirac(), dist_exponential()))$get_type()
dist_mixture(list(dist_dirac(), dist_binomial()))$get_type()
```

Method get_components():

Usage:

```
Distribution$get_components()
```

Details: Get the component Distributions of a transformed Distribution.

Returns: A possibly empty list of Distributions

Examples:

```
dist_trunc(dist_exponential())$get_components()
dist_dirac()$get_components()
dist_mixture(list(dist_exponential(), dist_gamma()))$get_components()
```

Method is_discrete():

Usage:

```
Distribution$is_discrete()
```

Details: Check if a Distribution is discrete, i.e. it has a density with respect to the counting measure.

Returns: TRUE if the Distribution is discrete, FALSE otherwise. Note that mixed distributions are not discrete but can have point masses.

Examples:

```
dist_exponential()$is_discrete()
dist_dirac()$is_discrete()
```

Method `is_continuous()`:*Usage:*`Distribution$is_continuous()`

Details: Check if a Distribution is continuous, i.e. it has a density with respect to the Lebesgue measure.

Returns: TRUE if the Distribution is continuous, FALSE otherwise. Note that mixed distributions are not continuous.

Examples:

```
dist_exponential()$is_continuous()  
dist_dirac()$is_continuous()
```

Method `require_capability()`:*Usage:*

```
Distribution$require_capability(  
  caps,  
  fun_name = paste0(sys.call(-1)[[1]], "()")  
)
```

Arguments:

`caps` Character vector of Capabilities to require

`fun_name` Friendly text to use for generating the error message in case of failure.

Details: Ensure that a Distribution has all required capabilities. Will throw an error if any capability is missing.

Returns: Invisibly TRUE.

Examples:

```
dist_exponential()$require_capability("diff_density")
```

Method `get_dof()`:*Usage:*`Distribution$get_dof()`

Details: Get the number of degrees of freedom of a Distribution family. Only parameters without a fixed default are considered free.

Returns: An integer representing the degrees of freedom suitable e.g. for AIC calculations.

Examples:

```
dist_exponential()$get_dof()  
dist_exponential(rate = 1.0)$get_dof()
```

Method `get_placeholders()`:*Usage:*`Distribution$get_placeholders()`

Details: Get Placeholders of a Distribution family. Returns a list of free parameters of the family. Their values will be NULL.

If the Distribution has Distributions as parameters, placeholders will be computed recursively.

Returns: A named list containing any combination of (named or unnamed) lists and NULLs.

Examples:

```
dist_exponential()$get_placeholders()
dist_mixture(list(dist_dirac(), dist_exponential()))$get_placeholders()
```

Method get_params():

Usage:

```
Distribution$get_params(with_params = list())
```

Arguments:

`with_params` Optional parameter overrides with the same structure as `dist$get_params()`.
Given Parameter values are expected to be length 1.

Details: Get a full list of parameters, possibly including placeholders.

Returns: A list representing the (recursive) parameter structure of the Distribution with values for specified parameters and NULL for free parameters that are missing both in the Distributions parameters and in `with_params`.

Examples:

```
dist_mixture(list(dist_dirac(), dist_exponential()))$get_params(
  with_params = list(probs = list(0.5, 0.5))
)
```

Method tf_make_constants():

Usage:

```
Distribution$tf_make_constants(with_params = list())
```

Arguments:

`with_params` Optional parameter overrides with the same structure as `dist$tf_make_constants()`.
Given Parameter values are expected to be length 1.

Details: Get a list of constant TensorFlow parameters

Returns: A list representing the (recursive) constant parameters of the Distribution with values sppecified by parameters. Each constant is a TensorFlow Tensor of dtype floatx.

Method tf_compile_params():

Usage:

```
Distribution$tf_compile_params(input, name_prefix = "")
```

Arguments:

`input` A keras layer to bind all outputs to
`name_prefix` Prefix to use for layer names

Details: Compile distribution parameters into tensorflow outputs

Returns: A list with two elements

- `outputs` a flat list of keras output layers, one for each parameter.
- `output_inflater` a function taking keras output layers and transforming them into a list structure suitable for passing to the loss function returned by [tf_compile_model\(\)](#)

Method get_param_bounds():

Usage:

```
Distribution$get_param_bounds()
```

Details: Get Interval bounds on all Distribution parameters

Returns: A list representing the free (recursive) parameter structure of the Distribution with Interval objects as values representing the bounds of the respective free parameters.

Examples:

```
dist_mixture(
  list(dist_dirac(), dist_exponential()),
  probs = list(0.5, 0.5)
)$get_param_bounds()

dist_mixture(
  list(dist_dirac(), dist_exponential())
)$get_param_bounds()

dist_genpareto()$get_param_bounds()
dist_genpareto1()$get_param_bounds()
```

Method get_param_constraints():

Usage:

```
Distribution$get_param_constraints()
```

Details: Get additional (non-linear) equality constraints on Distribution parameters

Returns: NULL if the box constraints specified by dist\$get_param_bounds() are sufficient, or a function taking full Distribution parameters and returning either a numeric vector (which must be 0 for valid parameter combinations) or a list with elements

- **constraints:** The numeric vector of constraints
- **jacobian:** The Jacobi matrix of the constraints with respect to the parameters

Examples:

```
dist_mixture(
  list(dist_dirac(), dist_exponential())
)$get_param_constraints()
```

Method export_functions():

Usage:

```
Distribution$export_functions(
  name,
  envir = parent.frame(),
  with_params = list()
)
```

Arguments:

name common suffix of the exported functions

envir Environment to export the functions to

with_params Optional list of parameters to use as default values for the exported functions

Details: Export sampling, density, probability and quantile functions to plain R functions
Creates new functions in `envir` named `{r,d,p,q}<name>` which implement `dist$sample`,
`dist$density`, `dist$probability` and `dist$quantile` as plain functions with default arguments specified by `with_params` or the fixed parameters.

The resulting functions will have signatures taking all parameters as separate arguments.

Returns: Invisibly `NULL`.

Examples:

```
tmp_env <- new.env(parent = globalenv())
dist_exponential()$export_functions(
  name = "exp",
  envir = tmp_env,
  with_params = list(rate = 2.0)
)
evalq(
  fitdistrplus::fitdist(rexp(100), "exp"),
  envir = tmp_env
)
```

Method `clone()`: The objects of this class are cloneable with this method.

Usage:

```
Distribution$clone(deep = FALSE)
```

Arguments:

`deep` Whether to make a deep clone.

dist_bdegp*Construct a BDEGP-Family***Description**

Constructs a BDEGP-Family distribution with fixed number of components and blending interval.

Usage

```
dist_bdegp(n, m, u, epsilon)
```

Arguments

- n Number of dirac components, starting with a point mass at 0.
- m Number of erlang components, translated by $n - 0.5$.
- u Blending cut-off, must be a positive real.
- epsilon Blending radius, must be a positive real less than u. The blending interval will be $u - \text{epsilon} < x < u + \text{epsilon}$.

Value

- A MixtureDistribution of
 - n DiracDistributions at 0 .. n - 1 and
 - a BlendedDistribution object with child Distributions
 - * a TranslatedDistribution with offset $n - 0.5$ of an ErlangMixtureDistribution with m shapes
 - * and a GeneralizedParetoDistribution with shape parameter restricted to [0, 1] and location parameter fixed at u With break u and bandwidth epsilon.

)

```

dist_beta

Beta Distribution

Description

See [stats::Beta](#)

Usage

```
dist_beta(shape1 = NULL, shape2 = NULL, ncp = NULL)
```

Arguments

shape1	First scalar shape parameter, or NULL as a placeholder.
shape2	Second scalar shape parameter, or NULL as a placeholder.
ncp	Scalar non-centrality parameter, or NULL as a placeholder.

Details

All parameters can be overridden with `with_params = list(shape = ..., scale = ...)`.

Value

A BetaDistribution object.

See Also

Other Distributions: [Distribution](#), [dist_bdegp\(\)](#), [dist_binomial\(\)](#), [dist_blended\(\)](#), [dist_dirac\(\)](#), [dist_discrete\(\)](#), [dist_empirical\(\)](#), [dist_erlangmix\(\)](#), [dist_exponential\(\)](#), [dist_gamma\(\)](#), [dist_genpareto\(\)](#), [dist_lognormal\(\)](#), [dist_mixture\(\)](#), [dist_negbinomial\(\)](#), [dist_normal\(\)](#), [dist_pareto\(\)](#), [dist_poisson\(\)](#), [dist_translate\(\)](#), [dist_trunc\(\)](#), [dist_uniform\(\)](#), [dist_weibull\(\)](#)

Examples

```
d_beta <- dist_beta(shape1 = 2, shape2 = 2, ncp = 0)
x <- d_beta$sample(100)
d_emp <- dist_empirical(x)

plot_distributions(
  empirical = d_emp,
  theoretical = d_beta,
  estimated = d_beta,
  with_params = list(
    estimated = inflate_params(
      fitdistrplus::fitdist(x, distr = "beta")$estimate
    )
  ),
  .x = seq(0, 2, length.out = 100)
)
```

dist_binomial *Binomial Distribution*

Description

See [stats::Binomial](#)

Usage

```
dist_binomial(size = NULL, prob = NULL)
```

Arguments

<code>size</code>	Number of trials parameter (integer), or <code>NULL</code> as a placeholder.
<code>prob</code>	Success probability parameter, or <code>NULL</code> as a placeholder.

Details

Both parameters can be overridden with `with_params = list(size = . . . , prob = . . .)`.

Value

A `BinomialDistribution` object.

See Also

Other Distributions: [Distribution](#), [dist_bdegp\(\)](#), [dist_beta\(\)](#), [dist_blended\(\)](#), [dist_dirac\(\)](#), [dist_discrete\(\)](#), [dist_empirical\(\)](#), [dist_erlangmix\(\)](#), [dist_exponential\(\)](#), [dist_gamma\(\)](#), [dist_genpareto\(\)](#), [dist_lognormal\(\)](#), [dist_mixture\(\)](#), [dist_negbinomial\(\)](#), [dist_normal\(\)](#), [dist_pareto\(\)](#), [dist_poisson\(\)](#), [dist_translate\(\)](#), [dist_trunc\(\)](#), [dist_uniform\(\)](#), [dist_weibull\(\)](#)

Examples

```
d_binom <- dist_binomial(size = 10, prob = 0.5)
x <- d_binom$sample(100)
d_emp <- dist_empirical(x)

plot_distributions(
  empirical = d_emp,
  theoretical = d_binom,
  estimated = d_binom,
  with_params = list(
    estimated = list(
      size = max(x),
      prob = mean(x) / max(x)
    )
  ),
  .x = 0:max(x)
)
```

Description

Blended distribution

Usage

```
dist_blended(dists, probs = NULL, breaks = NULL, bandwidths = NULL)
```

Arguments

dists	A list of $k \geq 2$ component Distributions.
probs	Mixture weight parameters
breaks	$k - 1$ Centers of the blending zones. <code>dists[i]</code> will blend into <code>dists[i + 1]</code> around <code>breaks[i]</code> .
bandwidths	$k - 1$ Radii of the blending zones. The i -th blending zone will begin at <code>breaks[i] - bandwidths[i]</code> and end at <code>breaks[i] + bandwidths[i]</code> . A bandwidth of 0 corresponds to a hard cut-off, i.e. a jump discontinuity in the density of the blended Distribution.

Value

A BlendedDistribution object.

Examples

```
bd <- dist_blended(
  list(
    dist_normal(mean = 0.0, sd = 1.0),
    dist_genpareto(u = 3.0, sigmau = 1.0, xi = 3.0)
  ),
  breaks = list(3.0),
  bandwidths = list(0.5),
  probs = list(0.9, 0.1)
)

plot_distributions(
  bd,
  .x = seq(-3, 10, length.out = 100),
  plots = c("d", "p")
)
```

Description

A degenerate distribution with all mass at a single point.

Usage

```
dist_dirac(point = NULL)
```

Arguments

point The point with probability mass 1.

Details

The parameter can be overridden with `with_params = list(point = ...)`.

Value

A DiracDistribution object.

See Also

Examples

```
d_dirac <- dist_dirac(1.5)
d_dirac$sample(2L)
d_dirac$sample(2L, list(point = 42.0))
```

dist_discrete *Discrete Distribution*

Description

A full-flexibility discrete distribution with values from 1 to `size`.

Usage

```
dist_discrete(size = NULL, probs = NULL)
```

Arguments

size Number of classes parameter (integer). Required if `probs` is `NULL`.
probs Vector of probabilities parameter, or `NULL` as a placeholder.

Details

Parameters can be overridden with `with_params = list(probs = ...)`.

Value

A DiscreteDistribution object.

See Also

Other Distributions: [Distribution](#), [dist_bdegp\(\)](#), [dist_beta\(\)](#), [dist_binomial\(\)](#), [dist_blended\(\)](#), [dist_dirac\(\)](#), [dist_empirical\(\)](#), [dist_erlangmix\(\)](#), [dist_exponential\(\)](#), [dist_gamma\(\)](#), [dist_genpareto\(\)](#), [dist_lognormal\(\)](#), [dist_mixture\(\)](#), [dist_negbinomial\(\)](#), [dist_normal\(\)](#), [dist_pareto\(\)](#), [dist_poisson\(\)](#), [dist_translate\(\)](#), [dist_trunc\(\)](#), [dist_uniform\(\)](#), [dist_weibull\(\)](#)

Examples

```
d_discrete <- dist_discrete(probs = list(0.5, 0.25, 0.15, 0.1))
x <- d_discrete$sample(100)
d_emp <- dist_empirical(x)

plot_distributions(
  empirical = d_emp,
  theoretical = d_discrete,
  estimated = d_discrete,
  with_params = list(
    estimated = list(
      size = max(x),
      probs = as.list(unname(table(x)) / 100)
    )
  ),
  .x = 0:max(x)
)
```

dist_empirical *Empirical distribution*

Description

Creates an empirical distribution object from a sample. Assumes iid. samples. `with_params` should **not** be used with this distribution because estimation of the relevant indicators happens during construction.

Usage

```
dist_empirical(sample, positive = FALSE, bw = "nrd0")
```

Arguments

sample	Sample to build the empirical distribution from
--------	---

<code>positive</code>	Is the underlying distribution known to be positive? This will effect the density estimation procedure. <code>positive = FALSE</code> uses a kernel density estimate produced by <code>density()</code> , <code>positive = TRUE</code> uses a log-kernel density estimate produced by <code>logKDE::logdensity_fft()</code> . The latter can improve density estimation near zero.
<code>bw</code>	Bandwidth parameter for density estimation. Passed to the density estimation function selected by <code>positive</code> .

Details

- `sample()` samples iid. from `sample`. This approach is similar to bootstrapping.
- `density()` evaluates a kernel density estimate, approximating with zero outside of the known support. This estimate is either obtained using `stats::density` or `logKDE::logdensity_fft`, depending on `positive`.
- `probability()` evaluates the empirical cumulative density function obtained by `stats::ecdf`.
- `quantile()` evaluates the empirical quantiles using `stats::quantile`
- `hazard()` estimates the hazard rate using the density estimate and the empirical cumulative density function: $h(t) = df(t) / (1 - cdf(t))$.

Value

An `EmpiricalDistribution` object.

Examples

```
x <- rexp(20, rate = 1)
dx <- dist_empirical(sample = x, positive = TRUE)

y <- rnorm(20)
dy <- dist_empirical(sample = y)

plot_distributions(
  exponential = dx,
  normal = dy,
  .x = seq(-3, 3, length.out = 100)
)
```

dist_erlangmix	<i>Erlang Mixture distribution</i>
----------------	------------------------------------

Description

Erlang Mixture distribution

Usage

```
dist_erlangmix(shapes, scale = NULL, probs = NULL)
```

Arguments

- | | |
|--------|--|
| shapes | Shape parameters, a trunc_erlangmix fit, or NULL as a placeholder. |
| scale | Common scale parameter, or NULL as a placeholder. |
| probs | Mixing probabilities, or NULL as a placeholder. |

Value

An ErlangMixtureDistribution object.

See Also

Other Distributions: [Distribution](#), [dist_bdegp\(\)](#), [dist_beta\(\)](#), [dist_binomial\(\)](#), [dist_blended\(\)](#), [dist_dirac\(\)](#), [dist_discrete\(\)](#), [dist_empirical\(\)](#), [dist_exponential\(\)](#), [dist_gamma\(\)](#), [dist_genpareto\(\)](#), [dist_lognormal\(\)](#), [dist_mixture\(\)](#), [dist_negbinomial\(\)](#), [dist_normal\(\)](#), [dist_pareto\(\)](#), [dist_poisson\(\)](#), [dist_translate\(\)](#), [dist_trunc\(\)](#), [dist_uniform\(\)](#), [dist_weibull\(\)](#)

Examples

```
params <- list(scale = 1.0, probs = list(0.5, 0.3, 0.2), shapes = list(1L, 2L, 3L))
dist <- dist_erlangmix(vector("list", 3L))
x <- dist$sample(20, with_params = params)
d_emp <- dist_empirical(x, positive = TRUE)

plot_distributions(
  empirical = d_emp,
  theoretical = dist,
  with_params = list(
    theoretical = params
  ),
  .x = seq(1e-4, 5, length.out = 100)
)
```

`dist_exponential` *Exponential distribution*

Description

See [stats::Exponential](#).

Usage

```
dist_exponential(rate = NULL)
```

Arguments

`rate` Scalar rate parameter, or `NULL` as a placeholder.

Details

The parameter can be overridden with `with_params = list(rate = ...)`.

Value

An `ExponentialDistribution` object.

See Also

Other Distributions: [Distribution](#), [dist_bdegp\(\)](#), [dist_beta\(\)](#), [dist_binomial\(\)](#), [dist_blended\(\)](#), [dist_dirac\(\)](#), [dist_discrete\(\)](#), [dist_empirical\(\)](#), [dist_erlangmix\(\)](#), [dist_gamma\(\)](#), [dist_genpareto\(\)](#), [dist_lognormal\(\)](#), [dist_mixture\(\)](#), [dist_negbinomial\(\)](#), [dist_normal\(\)](#), [dist_pareto\(\)](#), [dist_poisson\(\)](#), [dist_translate\(\)](#), [dist_trunc\(\)](#), [dist_uniform\(\)](#), [dist_weibull\(\)](#)

Examples

```
rate <- 1
d_exp <- dist_exponential()
x <- d_exp$sample(20, with_params = list(rate = rate))
d_emp <- dist_empirical(x, positive = TRUE)

plot_distributions(
  empirical = d_emp,
  theoretical = d_exp,
  estimated = d_exp,
  with_params = list(
    theoretical = list(rate = rate),
    estimated = list(rate = 1 / mean(x)))
),
.x = seq(1e-4, 5, length.out = 100)
)
```

dist_gamma*Gamma distribution*

Description

See [stats::GammaDist](#).

Usage

```
dist_gamma(shape = NULL, rate = NULL)
```

Arguments

shape	Scalar shape parameter, or NULL as a placeholder.
rate	Scalar rate parameter, or NULL as a placeholder.

Details

Both parameters can be overridden with `with_params = list(shape = ... , rate = ...)`.

Value

A `GammaDistribution` object.

See Also

Other Distributions: [Distribution](#), [dist_bdegp\(\)](#), [dist_beta\(\)](#), [dist_binomial\(\)](#), [dist_blended\(\)](#), [dist_dirac\(\)](#), [dist_discrete\(\)](#), [dist_empirical\(\)](#), [dist_erlangmix\(\)](#), [dist_exponential\(\)](#), [dist_genpareto\(\)](#), [dist_lognormal\(\)](#), [dist_mixture\(\)](#), [dist_negbinomial\(\)](#), [dist_normal\(\)](#), [dist_pareto\(\)](#), [dist_poisson\(\)](#), [dist_translate\(\)](#), [dist_trunc\(\)](#), [dist_uniform\(\)](#), [dist_weibull\(\)](#)

Examples

```
alpha <- 2
beta <- 2

d_gamma <- dist_gamma(shape = alpha, rate = beta)
x <- d_gamma$sample(100)
d_emp <- dist_empirical(x, positive = TRUE)

plot_distributions(
  empirical = d_emp,
  theoretical = d_gamma,
  estimated = d_gamma,
  with_params = list(
    estimated = inflate_params(
      fitdistrplus::fitdist(x, distr = "gamma")$estimate
    )
  ),
)
```

```
.x = seq(1e-3, max(x), length.out = 100)
)
```

dist_genpareto *Generalized Pareto Distribution*

Description

See [evmix::gpd](#)

Usage

```
dist_genpareto(u = NULL, sigmau = NULL, xi = NULL)

dist_genpareto1(u = NULL, sigmau = NULL, xi = NULL)
```

Arguments

u	Scalar location parameter, or NULL as a placeholder.
sigmau	Scalar scale parameter, or NULL as a placeholder.
xi	Scalar shape parameter, or NULL as a placeholder.

Details

All parameters can be overridden with `with_params = list(u = ..., sigmau = ..., xi = ...)`.

`dist_genpareto1` is equivalent to `dist_genpareto` but enforces bound constraints on `xi` to $[0, 1]$. This ensures unboundedness and finite expected value unless `xi == 1.0`.

Value

A `GeneralizedParetoDistribution` object.

)
```

dist_lognormal *Log Normal distribution*

Description

See [stats::Lognormal](#).

Usage

```
dist_lognormal(meanlog = NULL, sdlog = NULL)
```

Arguments

- | | |
|---------|---|
| meanlog | Scalar mean parameter on the log scale, or NULL as a placeholder. |
| sdlog | Scalar standard deviation parameter on the log scale, or NULL as a placeholder. |

Details

Both parameters can be overridden with `with_params = list(meanlog = ..., sdlog = ...)`.

Value

A `LognormalDistribution` object.

    )
  ),
  .x = seq(1e-3, 5, length.out = 100)
)

```

dist_mixture

Mixture distribution

Description

Parameters of mixing components can be overridden with `with_params = list(dists = list(..., ...))`. #’ Mixing probabilities can be overridden with `with_params = list(probs = list(..., ...))`. The **number of components** cannot be overridden.

Usage

```
dist_mixture(dists = list(), probs = NULL)
```

Arguments

- | | |
|--------------------|---|
| <code>dists</code> | A list of mixing distributions. May contain placeholders and duplicates. |
| <code>probs</code> | A list of mixing probabilities with the same length as <code>dists</code> . They are normalized to sum to one and <code>NULL</code> can be used as a placeholder within <code>probs</code> . To reduce the number of required parameters, <code>probs</code> should at least be partly specified (<code>probs = list(NULL, NULL, ..., 1)</code> with $k - 1$ <code>NULLs</code> where k is the number of mixing components). |

Details

Does **not** support the `quantile()` capability!

Value

A MixtureDistribution object.

Examples

```
# A complicated way to define a uniform distribution on \[0, 2\]
dist_mixture(
  dists = list(
    dist_uniform(min = 0, max = 1),
    dist_uniform(min = 1, max = 2)
  ),
  probs = list(0.5, 0.5)
)
```

dist_negbinomial *Negative binomial Distribution*

Description

See [stats::NegBinomial](#)

Usage

```
dist_negbinomial(size = NULL, mu = NULL)
```

Arguments

<code>size</code>	Number of successful trials parameter, or <code>NULL</code> as a placeholder. Non-integer values > 0 are allowed.
<code>mu</code>	Mean parameter, or <code>NULL</code> as a placeholder.

Details

Both parameters can be overridden with `with_params = list(size = . . . , prob = . . .)`.

Value

A NegativeBinomialDistribution object.

```
d_nbinom <- dist_negbinomial(size = 3.5, mu = 8.75)
x <- d_nbinom$sample(100)
d_emp <- dist_empirical(x)

plot_distributions(
  empirical = d_emp,
  theoretical = d_nbinom,
  estimated = d_nbinom,
  with_params = list(
    estimated = inflate_params(
      fitdistrplus::fitdist(x, distr = "nbinom")$estimate
    )
  ),
  .x = 0:max(x)
)
```

dist_normal*Normal distribution***Description**

See [stats::Normal](#).

Usage

```
dist_normal(mean = NULL, sd = NULL)
```

Arguments

- | | |
|-------------------|---|
| <code>mean</code> | Scalar mean parameter, or <code>NULL</code> as a placeholder. |
| <code>sd</code> | Scalar standard deviation parameter, or <code>NULL</code> as a placeholder. |

Details

Both parameters can be overridden with `with_params = list(mean = ..., sd = ...)`.

Value

A `NormalDistribution` object.

See Also

Other Distributions: [Distribution](#), [dist_bdegp\(\)](#), [dist_beta\(\)](#), [dist_binomial\(\)](#), [dist_blended\(\)](#), [dist_dirac\(\)](#), [dist_discrete\(\)](#), [dist_empirical\(\)](#), [dist_erlangmix\(\)](#), [dist_exponential\(\)](#), [dist_gamma\(\)](#), [dist_genpareto\(\)](#), [dist_lognormal\(\)](#), [dist_mixture\(\)](#), [dist_negbinomial\(\)](#), [dist_pareto\(\)](#), [dist_poisson\(\)](#), [dist_translate\(\)](#), [dist_trunc\(\)](#), [dist_uniform\(\)](#), [dist_weibull\(\)](#)

  ),
  .x = seq(-3, 3, length.out = 100)
)
```

dist_pareto*Pareto Distribution***Description**

See [Pareto](#)

Usage

```
dist_pareto(shape = NULL, scale = NULL)
```

Arguments

- | | |
|-------|---|
| shape | Scalar shape parameter, or NULL as a placeholder. |
| scale | Scalar scale parameter, or NULL as a placeholder. |

Details

Both parameters can be overridden with `with_params = list(shape = ..., scale = ...)`.

Value

A `ParetoDistribution` object.

    )
  ),
  .x = seq(0, 2, length.out = 100)
)
```

dist_poisson*Poisson Distribution***Description**

See [stats::Poisson](#)

Usage

```
dist_poisson(lambda = NULL)
```

Arguments

lambda Scalar rate parameter, or NULL as a placeholder.

Details

The parameter can be overridden with `with_params = list(lambda = ...)`.

Value

A PoissonDistribution object.

See Also

Other Distributions: [Distribution](#), [dist_bdegp\(\)](#), [dist_beta\(\)](#), [dist_binomial\(\)](#), [dist_blended\(\)](#), [dist_dirac\(\)](#), [dist_discrete\(\)](#), [dist_empirical\(\)](#), [dist_erlangmix\(\)](#), [dist_exponential\(\)](#), [dist_gamma\(\)](#), [dist_genpareto\(\)](#), [dist_lognormal\(\)](#), [dist_mixture\(\)](#), [dist_negbinomial\(\)](#), [dist_normal\(\)](#), [dist_pareto\(\)](#), [dist_translate\(\)](#), [dist_trunc\(\)](#), [dist_uniform\(\)](#), [dist_weibull\(\)](#)

Examples

```
d_pois <- dist_poisson(lambda = 5.0)
x <- d_pois$sample(100)
d_emp <- dist_empirical(x)

plot_distributions(
  empirical = d_emp,
  theoretical = d_pois,
  estimated = d_pois,
  with_params = list(
    estimated = inflate_params(
      fitdistrplus::fitdist(x, distr = "pois")$estimate
    )
  ),
  .x = 0:max(x)
)
```

dist_translate	<i>Tranlsated distribution</i>
----------------	--------------------------------

Description

Tranlsated distribution

Usage

```
dist_translate(dist = NULL, offset = NULL, multiplier = 1)
```

Arguments

- dist** An underlying distribution, or NULL as a placeholder.
- offset** Offset to be added to each observation, or NULL as a placeholder.
- multiplier** Factor to multiply each observation by, or NULL as a placeholder.

Value

A TranslatedDistribution object.

See Also

Other Distributions: [Distribution](#), [dist_bdegp\(\)](#), [dist_beta\(\)](#), [dist_binomial\(\)](#), [dist_blended\(\)](#), [dist_dirac\(\)](#), [dist_discrete\(\)](#), [dist_empirical\(\)](#), [dist_erlangmix\(\)](#), [dist_exponential\(\)](#), [dist_gamma\(\)](#), [dist_genpareto\(\)](#), [dist_lognormal\(\)](#), [dist_mixture\(\)](#), [dist_negbinomial\(\)](#), [dist_normal\(\)](#), [dist_pareto\(\)](#), [dist_poisson\(\)](#), [dist_trunc\(\)](#), [dist_uniform\(\)](#), [dist_weibull\(\)](#)

Examples

```
d_norm <- dist_normal(mean = 0, sd = 1)
d_tnorm <- dist_translate(dist = d_norm, offset = 1)
plot_distributions(d_norm, d_tnorm, .x = seq(-2, 3, length.out = 100))
```

dist_trunc*Truncated distribution***Description**

Truncated distribution

Usage

```
dist_trunc(dist = NULL, min = NULL, max = NULL, offset = 0, max_retry = 100)
```

Arguments

<code>dist</code>	An underlying distribution, or <code>NULL</code> as a placeholder.
<code>min</code>	Minimum value to truncate at (exclusive), or <code>NULL</code> as a placeholder.
<code>max</code>	Maxmimum value to truncate at (inclusive), or <code>NULL</code> as a placeholder.
<code>offset</code>	Offset to be added to each observation after truncation, or <code>NULL</code> as a placeholder. Truncation of <code>dist</code> will occur to $(\text{min}, \text{max}]$. The offset is then added deterministically.
<code>max_retry</code>	Maximum number of resample attempts when trying to sample with rejection.

Value

A `TruncatedDistribution` object.

See Also

d_tnorm <- dist_trunc(dist = d_norm, min = -2, max = 2, offset = 1)
plot_distributions(d_norm, d_tnorm, .x = seq(-2, 3, length.out = 100))
```

`dist_uniform`

Uniform distribution

Description

See [stats::Uniform](#)

Usage

```
dist_uniform(min = NULL, max = NULL)
```

Arguments

- | | |
|------------------|---|
| <code>min</code> | Lower limit, or <code>NULL</code> as a placeholder. |
| <code>max</code> | Upper limit, or <code>NULL</code> as a placeholder. |

Details

Both parameters can be overridden with `with_params = list(min = ..., max = ...)`.

Value

A `UniformDistribution` object.

  estimated = d_unif,
  with_params = list(
```

```

estimated = inflate_params(
  fitdistrplus::fitdist(x, distr = "unif")$estimate
)
),
.x = seq(0, 1, length.out = 100)
)

```

dist_weibull*Weibull Distribution***Description**

See [stats::Weibull](#)

Usage

```
dist_weibull(shape = NULL, scale = NULL)
```

Arguments

- | | |
|-------|---|
| shape | Scalar shape parameter, or NULL as a placeholder. |
| scale | Scalar scale parameter, or NULL as a placeholder. |

Details

Both parameters can be overridden with `with_params = list(shape = . . . , scale = . . .)`.

Value

A `WeibullDistribution` object.

See Also

  estimated = d_weibull,

```

```

with_params = list(
  estimated = inflate_params(
    fitdistrplus::fitdist(x, distr = "weibull")$estimate
  )
),
.x = seq(0, 2, length.out = 100)
)

```

fit.reservr_keras_model*Fit a neural network based distribution model to data***Description**

This function delegates most work to `keras3::fit.keras.src.models.model.Model()` and performs additional consistency checks to make sure `tf_compile_model()` was called with the appropriate options to support fitting the observations `y` as well as automatically converting `y` to a $n \times 6$ matrix needed by the compiled loss function.

Usage

```

## S3 method for class 'reservr_keras_model'
fit(
  object,
  x,
  y,
  batch_size = NULL,
  epochs = 10,
  verbose = getOption("keras.fit_verbose", default = 1),
  callbacks = NULL,
  view_metrics = getOption("keras.view_metrics", default = "auto"),
  validation_split = 0,
  validation_data = NULL,
  shuffle = TRUE,
  class_weight = NULL,
  sample_weight = NULL,
  initial_epoch = 0,
  steps_per_epoch = NULL,
  validation_steps = NULL,
  ...
)

```

Arguments

- | | |
|---------------------|--|
| <code>object</code> | A compiled <code>reservr_keras_model</code> as obtained by <code>tf_compile_model()</code> . |
| <code>x</code> | A list of input tensors (predictors) |

y	A trunc_obs tibble of observed outcomes, or something convertible via <code>as_trunc_obs()</code> .
batch_size	Integer or NULL. Number of samples per gradient update. If unspecified, batch_size will default to 32. Do not specify the batch_size if your data is in the form of TF Datasets or generators, (since they generate batches).
epochs	Integer. Number of epochs to train the model. An epoch is an iteration over the entire x and y data provided (unless the steps_per_epoch flag is set to something other than NULL). Note that in conjunction with initial_epoch, epochs is to be understood as "final epoch". The model is not trained for a number of iterations given by epochs, but merely until the epoch of index epochs is reached.
verbose	"auto", 0, 1, or 2. Verbosity mode. 0 = silent, 1 = progress bar, 2 = one line per epoch. "auto" becomes 1 for most cases, 2 if in a knitr render or running on a distributed training server. Note that the progress bar is not particularly useful when logged to a file, so verbose=2 is recommended when not running interactively (e.g., in a production environment). Defaults to "auto".
callbacks	List of <code>Callback()</code> instances. List of callbacks to apply during training. See <code>callback_*</code> .
view_metrics	View realtime plot of training metrics (by epoch). The default ("auto") will display the plot when running within RStudio, metrics were specified during model <code>compile()</code> , epochs > 1 and verbose > 0. Set the global options(<code>keras.view_metrics = </code>) option to establish a different default.
validation_split	Float between 0 and 1. Fraction of the training data to be used as validation data. The model will set apart this fraction of the training data, will not train on it, and will evaluate the loss and any model metrics on this data at the end of each epoch. The validation data is selected from the last samples in the x and y data provided, before shuffling. This argument is not supported when x is a TF Dataset or generator. If both validation_data and validation_split are provided, validation_data will override validation_split.
validation_data	Data on which to evaluate the loss and any model metrics at the end of each epoch. The model will not be trained on this data. Thus, note the fact that the validation loss of data provided using validation_split or validation_data is not affected by regularization layers like noise and dropout. validation_data will override validation_split. It could be: <ul style="list-style-type: none"> • A tuple (<code>x_val</code>, <code>y_val</code>) of arrays or tensors. • A tuple (<code>x_val</code>, <code>y_val</code>, <code>val_sample_weights</code>) of arrays. • A generator returning (<code>inputs</code>, <code>targets</code>) or (<code>inputs</code>, <code>targets</code>, <code>sample_weights</code>).
shuffle	Boolean, whether to shuffle the training data before each epoch. This argument is ignored when x is a generator or a TF Dataset.
class_weight	Optional named list mapping class indices (integers, 0-based) to a weight (float) value, used for weighting the loss function (during training only). This can be useful to tell the model to "pay more attention" to samples from an under-represented class. When class_weight is specified and targets have a rank of 2 or greater, either y must be one-hot encoded, or an explicit final dimension of 1 must be included for sparse class labels.

<code>sample_weight</code>	Optional array of weights for the training samples, used for weighting the loss function (during training only). You can either pass a flat (1D) array/vector with the same length as the input samples (1:1 mapping between weights and samples), or in the case of temporal data, you can pass a 2D array (matrix) with shape (<code>samples</code> , <code>sequence_length</code>), to apply a different weight to every timestep of every sample. This argument is not supported when <code>x</code> is a TF Dataset or generator, instead provide the <code>sample_weights</code> as the third element of <code>x</code> . Note that sample weighting does not apply to metrics specified via the <code>metrics</code> argument in <code>compile()</code> . To apply sample weighting to your metrics, you can specify them via the <code>weighted_metrics</code> in <code>compile()</code> instead.
<code>initial_epoch</code>	Integer. Epoch at which to start training (useful for resuming a previous training run).
<code>steps_per_epoch</code>	Integer or NULL. Total number of steps (batches of samples) before declaring one epoch finished and starting the next epoch. When training with input tensors such as backend-native tensors, the default NULL is equal to the number of samples in your dataset divided by the batch size, or 1 if that cannot be determined. If <code>x</code> is a TF Dataset, and <code>steps_per_epoch</code> is NULL, the epoch will run until the input dataset is exhausted. When passing an infinitely repeating dataset, you must specify the <code>steps_per_epoch</code> argument. If <code>steps_per_epoch = -1</code> the training will run indefinitely with an infinitely repeating dataset.
<code>validation_steps</code>	Only relevant if <code>validation_data</code> is provided. Total number of steps (batches of samples) to draw before stopping when performing validation at the end of every epoch. If <code>validation_steps</code> is NULL, validation will run until the <code>validation_data</code> dataset is exhausted. In the case of an infinitely repeated dataset, it will run into an infinite loop. If <code>validation_steps</code> is specified and only part of the dataset will be consumed, the evaluation will start from the beginning of the dataset at each epoch. This ensures that the same validation samples are used every time.
<code>...</code>	Unused. If old arguments are supplied, an error message will be raised informing how to fix the issue.

Details

Additionally, the default `batch_size` is `min(nrow(y), 10000)` instead of keras default of 32 because the latter is a very bad choice for fitting most distributions since the involved loss is much less stable than typical losses used in machine learning, leading to divergence for small batch sizes.

Value

A history object that contains all information collected during training. The model object will be updated in-place as a side-effect.

    )
  )
}

```

fit.blended

Fit a Blended mixture using an ECME-Algorithm

Description

Fit a Blended mixture using an ECME-Algorithm

Usage

```

fit.blended(
  dist,
  obs,
  start,
  min_iter = 0L,
  max_iter = 100L,
  skip_first_e = FALSE,
  tolerance = 1e-05,
  trace = FALSE,
  ...
)

```

Arguments

dist	A BlendedDistribution. It is assumed, that breaks and bandwidths are not a placeholder and that weights are to be estimated.
obs	Set of observations as produced by <code>trunc_obs()</code> or convertible via <code>as_trunc_obs()</code> .
start	Initial values of all placeholder parameters. If missing, starting values are obtained from <code>fit_dist_start()</code> .
min_iter	Minimum number of EM-Iterations
max_iter	Maximum number of EM-Iterations (weight updates)
skip_first_e	Skip the first E-Step (update Probability weights)? This can help if the initial values cause a mixture component to vanish in the first E-Step before the starting values can be improved.
tolerance	Numerical tolerance.
trace	Include tracing information in output? If TRUE, additional tracing information will be added to the result list.
...	Passed to <code>fit_dist_start()</code> if start is missing.

Value

A list with elements

- params the fitted parameters in the same structure as init.
- params_hist (if trace is TRUE) the history of parameters (after each e- and m- step)
- iter the number of outer EM-iterations
- logLik the final log-likelihood

See Also

Other distribution fitting functions: `fit_dist()`, `fit_erlang_mixture()`, `fit_mixture()`

Examples

```
dist <- dist.blended(
  list(
    dist_exponential(),
    dist_genpareto()
  )
)

params <- list(
  probs = list(0.9, 0.1),
  dists = list(
    list(rate = 2.0),
    list(u = 1.5, xi = 0.2, sigmau = 1.0)
  ),
  breaks = list(1.5),
  bandwidths = list(0.3)
)
```

```

x <- dist$sample(100L, with_params = params)

dist$default_params$breaks <- params$breaks
dist$default_params$bandwidths <- params$bandwidths
if (interactive()) {
  fit_blended(dist, x)
}

```

fit_dist*Fit a general distribution to observations***Description**

The default implementation performs maximum likelihood estimation on all placeholder parameters.

Usage

```

fit_dist(dist, obs, start, ...)
fit_dist_direct(dist, obs, start, ..., .start_with_default = FALSE)
## S3 method for class 'Distribution'
fit(object, obs, start, ...)

```

Arguments

<code>dist</code>	A <code>Distribution</code> object.
<code>obs</code>	Set of observations as produced by <code>trunc_obs()</code> or convertible via <code>as_trunc_obs()</code> .
<code>start</code>	Initial values of all placeholder parameters. If missing, starting values are obtained from <code>fit_dist_start()</code> .
<code>...</code>	Distribution-specific arguments for the fitting procedure
<code>.start_with_default</code>	Before directly optimising the likelihood, use an optimised algorithm for finding better starting values?
<code>object</code>	same as parameter <code>dist</code>

Details

For Erlang mixture distributions and for Mixture distributions, an EM-Algorithm is instead used to improve stability.

`fit()` and `fit_dist()` will chose an optimisation method optimized for the specific distribution given. `fit_dist_direct()` can be used to force direct maximisation of the likelihood.

Value

A list with at least the elements

- `params` the fitted parameters in the same structure as `init`.
- `logLik` the final log-likelihood

Additional information may be provided depending on `dist`.

Other distribution fitting functions: [fit_blended\(\)](#), [fit_erlang_mixture\(\)](#), [fit_mixture\(\)](#)

Examples

```
x <- rexp(100)
lambda_hat <- 1 / mean(x)
lambda_hat2 <- fit_dist(dist_exponential(), x)$params$rate
identical(lambda_hat, lambda_hat2)
dist <- dist_mixture(list(dist_normal(), dist_translate(dist_exponential(), offset = 6)))
params <- list(
  dists = list(list(mean = 5, sd = 1), list(dist = list(rate = 1))), probs = list(0.95, 0.05)
)
set.seed(2000)
u <- runif(100, 10, 20)
x <- dist$sample(100, with_params = params)
obs <- trunc_obs(x = x[x <= u], tmin = -Inf, tmax = u[x <= u])

default_fit <- fit_dist(dist, obs)
direct_fit <- fit_dist_direct(dist, obs)
# NB: direct optimisation steps with pre-run take a few seconds

direct_fit_init <- fit_dist_direct(dist, obs, start = default_fit$params)
direct_fit_auto_init <- fit_dist_direct(dist, obs, .start_with_default = TRUE)

stopifnot(direct_fit_init$logLik == direct_fit_auto_init$logLik)

c(default_fit$logLik, direct_fit$logLik, direct_fit_init$logLik)
```

fit_dist_start.MixtureDistribution

Find starting values for distribution parameters

Description

Find starting values for distribution parameters

Usage

```
## S3 method for class 'MixtureDistribution'
fit_dist_start(dist, obs, dists_start = NULL, ...)

fit_dist_start(dist, obs, ...)
```

Arguments

<code>dist</code>	A Distribution object.
<code>obs</code>	Observations to fit to.
<code>dists_start</code>	List of initial parameters for all component distributions. If left empty, initialisation will be automatically performed using <code>fit_dist_start()</code> with all observations in the support of each respective component.
<code>...</code>	Additional arguments for the initialisation procedure

Value

A list of initial parameters suitable for passing to `fit_dist()`.

Examples

```
fit_dist_start(dist_exponential(), rexp(100))
```

`fit_erlang_mixture` *Fit an Erlang mixture using an ECME-Algorithm*

Description

Fit an Erlang mixture using an ECME-Algorithm

Usage

```
fit_erlang_mixture(
  dist,
  obs,
  start,
  min_iter = 0L,
  max_iter = 100L,
  skip_first_e = FALSE,
  tolerance = 1e-05,
  trace = FALSE,
  parallel = FALSE,
  ...
)
```

Arguments

<code>dist</code>	An ErlangMixtureDistribution. It is assumed, that both <code>probs</code> and <code>scale</code> are to be estimated.
<code>obs</code>	Set of observations as produced by <code>trunc_obs()</code> or convertible via <code>as_trunc_obs()</code> .
<code>start</code>	Initial values of all placeholder parameters. If missing, starting values are obtained from <code>fit_dist_start()</code> .
<code>min_iter</code>	Minimum number of EM-Iterations
<code>max_iter</code>	Maximum number of EM-Iterations (weight updates)
<code>skip_first_e</code>	Skip the first E-Step (update Probability weights)? This can help if the initial values cause a mixture component to vanish in the first E-Step before the starting values can be improved.
<code>tolerance</code>	Numerical tolerance.
<code>trace</code>	Include tracing information in output? If TRUE, additional tracing information will be added to the result list.
<code>parallel</code>	Enable experimental parallel evaluation of expected log-likelihood?
<code>...</code>	Passed to <code>fit_dist_start()</code> if <code>start</code> is missing.

Value

A list with elements

- `params` the fitted parameters in the same structure as `init`.
- `params_hist` (if `trace` is TRUE) the history of parameters (after each e- and m- step). Otherwise an empty list.
- `iter` the number of outer EM-iterations
- `logLik` the final log-likelihood

See Also

Other distribution fitting functions: `fit_blended()`, `fit_dist()`, `fit_mixture()`

Examples

```
dist <- dist_erlangmix(list(NULL, NULL, NULL))
params <- list(
  shapes = list(1L, 4L, 12L),
  scale = 2.0,
  probs = list(0.5, 0.3, 0.2)
)
x <- dist$sample(100L, with_params = params)
fit_erlang_mixture(dist, x, init = "kmeans")
```

fit_mixture*Fit a generic mixture using an ECME-Algorithm*

Description

Fit a generic mixture using an ECME-Algorithm

Usage

```
fit_mixture(
  dist,
  obs,
  start,
  min_iter = 0L,
  max_iter = 100L,
  skip_first_e = FALSE,
  tolerance = 1e-05,
  trace = FALSE,
  ...
)
```

Arguments

<code>dist</code>	A MixtureDistribution specifying the structure of the mixture. Free parameters are to be optimised. The dominating measure for likelihoods must be constant, so for example <code>dist_dirac()</code> may not have its point parameter free.
<code>obs</code>	Set of observations as produced by <code>trunc_obs()</code> or convertible via <code>as_trunc_obs()</code> .
<code>start</code>	Initial values of all placeholder parameters. If missing, starting values are obtained from <code>fit_dist_start()</code> .
<code>min_iter</code>	Minimum number of EM-Iterations
<code>max_iter</code>	Maximum number of EM-Iterations (weight updates)
<code>skip_first_e</code>	Skip the first E-Step (update Probability weights)? This can help if the initial values cause a mixture component to vanish in the first E-Step before the starting values can be improved.
<code>tolerance</code>	Numerical tolerance.
<code>trace</code>	Include tracing information in output? If TRUE, additional tracing information will be added to the result list.
<code>...</code>	Passed to <code>fit_dist_start()</code> if <code>start</code> is missing.

Value

A list with elements

- `params` the fitted parameters in the same structure as `init`.
- `params_hist` (if `trace` is TRUE) the history of parameters (after each e- and m- step)

- `iter` the number of outer EM-iterations
- `logLik` the final log-likelihood

See Also

Other distribution fitting functions: `fit_blended()`, `fit_dist()`, `fit_erlang_mixture()`

Examples

```
dist <- dist_mixture(  
  list(  
    dist_dirac(0.0),  
    dist_exponential()  
  )  
)  
  
params <- list(  
  probs = list(0.1, 0.9),  
  dists = list(  
    list(),  
    list(rate = 1.0)  
  )  
)  
  
x <- dist$sample(100L, with_params = params)  
  
fit_mixture(dist, x)
```

flatten_params *Flatten / Inflate parameter lists / vectors*

Description

Flatten / Inflate parameter lists / vectors

Usage

```
flatten_params(params)  
  
flatten_params_matrix(params)  
  
flatten_bounds(bounds)  
  
inflate_params(flat_params)
```

Arguments

<code>params</code>	A named list of parameters to be flattened. Should be in a form to be passed as the <code>with_params</code> argument to most distribution functions.
<code>bounds</code>	List of parameter bounds as returned by <code>dist\$get_param_bounds()</code>
<code>flat_params</code>	A named numeric vector of parameters

Value

`flatten_params` returns a 'flattened' vector of parameters. It is intended as an adapter for multi-dimensional optimisation functions to distribution objects.

`flatten_params_matrix` returns a 'flattened' matrix of parameters. It is intended as an adapter for multi-dimensional optimisation functions to distribution objects. Each column corresponds to one input element.

`flatten_bounds` returns a named list of vectors with names `lower` and `upper`. Containing the upper and lower bounds of each parameter.

`inflate_params` returns an 'inflated' list of parameters. This can be passed as the `with_params` argument to most distribution functions.

Examples

```
library(ggplot2)

mm <- dist_mixture(list(
  dist_exponential(NULL),
  dist_lognormal(0.5, NULL)
), list(NULL, 1))

ph <- mm$get_placeholders()
ph_flat <- flatten_params(ph)
ph_reinflated <- inflate_params(ph_flat)
ph_flat[] <- c(1, 1, 6)
ph_sample <- inflate_params(ph_flat)

x <- mm$sample(
  100,
  with_params = ph_sample
)

emp_cdf <- ecdf(x)

ggplot(data.frame(t = seq(from = min(x), to = max(x), length.out = 100))) %+%
  geom_point(aes(x = t, y = emp_cdf(t))) %+%
  geom_line(aes(x = t, y = mm$probability(t, with_params = ph_sample)),
            linetype = 2)
```

Description

These functions provide information about the generalized Pareto distribution with threshold u .
`dgp`d gives the density, `pgp`d gives the distribution function, `qgp`d gives the quantile function and
`rgp`d generates random deviates.

Usage

```
rgpd(n = 1L, u = 0, sigmau = 1, xi = 0)

dgp(x, u = 0, sigmau = 1, xi = 0, log = FALSE)

pgp(q, u = 0, sigmau = 1, xi = 0, lower.tail = TRUE, log.p = FALSE)

qgp(p, u = 0, sigmau = 1, xi = 0, lower.tail = TRUE, log.p = FALSE)
```

Arguments

<code>n</code>	integer number of observations.
<code>u</code>	threshold parameter (minimum value).
<code>sigmau</code>	scale parameter (must be positive).
<code>xi</code>	shape parameter
<code>x, q</code>	vector of quantiles.
<code>log, log.p</code>	logical; if TRUE, probabilities/densities <code>p</code> are given as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P(X \leq x)$, otherwise $P(X > x)$.
<code>p</code>	vector of probabilities.

Details

If u , σ_{mu} or ξ are not specified, they assume the default values of 0, 1 and 0 respectively.

The generalized Pareto distribution has density

$$f(x) = 1/\sigma_u (1 + \xi z)^{-1 - 1/\xi}$$

where $z = (x - u)/\sigma_u$ and $f(x) = \exp(-z)$ if ξ is 0. The support is $x \geq u$ for $\xi \geq 0$ and $u \leq x \leq u - \sigma_u/\xi$ for $\xi < 0$.

The Expected value exists if $\xi < 1$ and is equal to

$$E(X) = u + \sigma_u/(1 - \xi)$$

k -th moments exist in general for $k\xi < 1$.

Value

`rgpd` generates random deviates.
`dgpd` gives the density.
`pgpd` gives the distribution function.
`qgpd` gives the quantile function.

References

https://en.wikipedia.org/wiki/Generalized_Pareto_distribution

Examples

```
x <- rgpd(1000, u = 1, sigmau = 0.5, xi = 0.1)
xx <- seq(-1, 10, 0.01)
hist(x, breaks = 100, freq = FALSE, xlim = c(-1, 10))
lines(xx, dgpd(xx, u = 1, sigmau = 0.5, xi = 0.1))

plot(xx, dgpd(xx, u = 1, sigmau = 1, xi = 0), type = "l")
lines(xx, dgpd(xx, u = 0.5, sigmau = 1, xi = -0.3), col = "blue", lwd = 2)
lines(xx, dgpd(xx, u = 1.5, sigmau = 1, xi = 0.3), col = "red", lwd = 2)

plot(xx, dgpd(xx, u = 1, sigmau = 1, xi = 0), type = "l")
lines(xx, dgpd(xx, u = 1, sigmau = 0.5, xi = 0), col = "blue", lwd = 2)
lines(xx, dgpd(xx, u = 1, sigmau = 2, xi = 0), col = "red", lwd = 2)
```

Description

Integrates `fun` over the bounds [`lower`, `upper`] vectorized over `lower` and `upper`. Vectorized list structures of parameters can also be passed.

Usage

```
integrate_gk(
  fun,
  lower,
  upper,
  params = list(),
  .tolerance = .Machine$double.eps^0.25,
  .max_iter = 100L
)
```

Arguments

<code>fun</code>	A function to integrate. Must be vectorized and take one or two arguments, the first being points to evaluate at and the second (optionally) being parameters to apply. It must return a numeric vector the same length as its first input. Currently, infinite bounds are not supported.
<code>lower, upper</code>	Integration bounds. Must have the same length.
<code>params</code>	Parameters to pass as a second argument to <code>fun</code> . The actual parameters must have the same length as the number of integrals to compute. Can be a possibly nested list structures containing numeric vectors. Alternatively, can be a matrix with the same number of rows as the number of integrals to compute.
<code>.tolerance</code>	Absolute element-wise tolerance.
<code>.max_iter</code>	Maximum number of iterations. The number of integration intervals will be at most <code>length(lower) * .max_iter</code> . Therefor the maximum number of function evaluations per integration interval will be <code>15 * .max_iter</code> .

Details

The integration error is estimated by the Gauss-Kronrod quadrature as the absolute difference between the 7-point quadrature and the 15-point quadrature. Integrals that did not converge will be bisected at the midpoint. The `params` object will be recursively subsetted on all numeric vectors with the same length as the number of observations.

Value

A vector of integrals with the `i`-th entry containing an approximation of the integral of `fun(t, pick_params_at(params, i)) dt` over the interval `lower[i]` to `upper[i]`

Examples

```
# Argument recycling and parallel integration of two intervals
integrate_gk(sin, 0, c(pi, 2 * pi))

dist <- dist_exponential()
integrate_gk(
  function(x, p) dist$density(x, with_params = p),
  lower = 0, upper = 1:10,
  params = list(rate = 1 / 1:10)
)
dist$probability(1:10, with_params = list(rate = 1 / 1:10))
```

interval*Intervals***Description**

Intervals

Usage

```
interval(
  range = c(-Inf, Inf),
  ...,
  include_lowest = closed,
  include_highest = closed,
  closed = FALSE,
  integer = FALSE,
  read_only = FALSE
)

is.Interval(x)
```

Arguments

<code>range</code>	The interval boundaries as a sorted two-element numeric vector.
<code>...</code>	First argument is used as the endpoint if <code>range</code> has length 1. Additional arguments, or any if <code>range</code> has length 2, cause a warning and will be ignored.
<code>include_lowest</code>	Is the lower boundary part of the interval?
<code>include_highest</code>	Is the upper boundary part of the interval?
<code>closed</code>	Is the interval closed?
<code>integer</code>	Is the interval only over the integers?
<code>read_only</code>	Make the interval object read-only?
<code>x</code>	An object.

Value

`interval` returns an `Interval`. `is.Interval` returns TRUE if `x` is an `Interval`, FALSE otherwise.

See Also

`interval-operations`

Examples

```
# The real line
interval()

# Closed unit interval
interval(c(0, 1), closed = TRUE)
# Alternative form
interval(0, 1, closed = TRUE)

# Non-negative real line
interval(c(0, Inf), include_lowest = TRUE)
```

interval-operations *Convex union and intersection of intervals*

Description

Convex union and intersection of intervals

Usage

```
interval_union(..., intervals = list())
interval_intersection(..., intervals = list())
```

Arguments

... appended to `intervals` if present.
intervals A list of Intervals.

Value

`interval_union` returns the convex union of all intervals in `intervals`. This is the smallest interval completely containing all intervals.

`interval_intersection` returns the set intersection of all intervals in `intervals`. The empty set is represented by the open interval (0, 0).

See Also

`interval`

Examples

```

interval_union(
  interval(c(0, 1), closed = TRUE),
  interval(c(1, 2))
)

interval_union(
  interval(c(0, 5)),
  interval(c(1, 4), closed = TRUE)
)

# Convex union is not equal to set union:
interval_union(
  interval(c(0, 1)),
  interval(c(2, 3))
)

# The empty union is {}
interval_union()

interval_intersection(
  interval(c(0, 1)),
  interval(c(0.5, 2))
)

interval_intersection(
  interval(c(0, Inf)),
  interval(c(-Inf, 0)))
)

interval_intersection(
  interval(c(0, Inf), include_lowest = TRUE),
  interval(c(-Inf, 0), include_highest = TRUE)
)

interval_intersection(
  interval(c(0, 5)),
  interval(c(1, 6), closed = TRUE)
)

# The empty intersection is (-Inf, Inf)
interval_intersection()

```

is.Distribution *Test if object is a Distribution*

Description

Test if object is a Distribution

Usage

```
is.Distribution(object)
```

Arguments

object An R object.

Value

TRUE if object is a Distribution, FALSE otherwise.

Examples

```
is.Distribution(dist_dirac())
```

k_matrix	<i>Cast to a TensorFlow matrix</i>
----------	------------------------------------

Description

Cast to a TensorFlow matrix

Usage

```
k_matrix(x, dtype = NULL)
```

Arguments

x Numeric object to be converted to a matrix Tensor.

dtype Type of the elements of the resulting tensor. Defaults to [keras3::config_floatx\(\)](#).

Value

A two-dimensional `tf.Tensor` with values from x. The shape will be `(nrow(x), ncol(x))` where x is first converted to an R matrix via [as.matrix\(\)](#).

Examples

```
if (interactive()) {
  k_matrix(diag(1:3))
  k_matrix(diag(1:3), dtype = "int32")
  # Vectors are converted to columns:
  k_matrix(1:3)
}
```

Pareto*The Pareto Distribution*

Description

These functions provide information about the Pareto distribution. `dpareto` gives the density, `ppareto` gives the distribution function, `qpareto` gives the quantile function and `rpareto` generates random deviates.

Usage

```
rpareto(n = 1L, shape = 0, scale = 1)

dpareto(x, shape = 1, scale = 1, log = FALSE)

ppareto(q, shape = 1, scale = 1, lower.tail = TRUE, log.p = FALSE)

qpareto(p, shape = 1, scale = 1, lower.tail = TRUE, log.p = FALSE)
```

Arguments

<code>n</code>	integer number of observations.
<code>shape</code>	shape parameter (must be positive).
<code>scale</code>	scale parameter (must be positive).
<code>x, q</code>	vector of quantiles.
<code>log, log.p</code>	logical; if TRUE, probabilities/densities <code>p</code> are given as <code>log(p)</code> .
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P(X \leq x)$, otherwise $P(X > x)$.
<code>p</code>	vector of probabilities.

Details

If `shape` or `scale` are not specified, they assume the default values of 1.

The Pareto distribution with scale θ and shape ξ has density

$$f(x) = \xi\theta^\xi / (x + \theta)^{\xi + 1}$$

The support is $x \geq 0$.

The Expected value exists if $\xi > 1$ and is equal to

$$E(X) = \theta / (\xi - 1)$$

k-th moments exist in general for $k < \xi$.

Value

rpareto generates random deviates.
dpareto gives the density.
ppareto gives the distribution function.
qpareto gives the quantile function.

References

https://en.wikipedia.org/wiki/Pareto_distribution - named Lomax therein.

Examples

```
x <- rpareto(1000, shape = 10, scale = 5)
xx <- seq(-1, 10, 0.01)
hist(x, breaks = 100, freq = FALSE, xlim = c(-1, 10))
lines(xx, dpareto(xx, shape = 10, scale = 5))

plot(xx, dpareto(xx, shape = 10, scale = 5), type = "l")
lines(xx, dpareto(xx, shape = 3, scale = 5), col = "red", lwd = 2)

plot(xx, dpareto(xx, shape = 10, scale = 10), type = "l")
lines(xx, dpareto(xx, shape = 10, scale = 5), col = "blue", lwd = 2)
lines(xx, dpareto(xx, shape = 10, scale = 20), col = "red", lwd = 2)
```

plot_distributions *Plot several distributions*

Description

Plot several distributions

Usage

```
plot_distributions(
  ...,
  distributions = list(),
  .x,
  plots = c("density", "probability", "hazard"),
  with_params = list(),
  as_list = FALSE
)
```

Arguments

...	distribution objects (must be named)
distributions	Named list of distribution objects. This is concatenated with
.x	Numeric vector of points to evaluate at.
plots	Plots to be created. May be abbreviated. The plots will be stacked in the order given from top to bottom.
with_params	list of distribution parameters to be given to each distribution using <code>with_params</code> . If named, the names are matched to the distribution names. Otherwise, they are allocated positionally, index 1 corresponding to the first element of <code>distributions</code> , then all other elements from <code>distributions</code> followed by the arguments in ... in order.
as_list	return a list of ggplots instead of a patchwork?

Value

A stacked patchwork of the requested ggplots

Examples

```
rate <- 1
x <- rexp(20, rate)
d_emp <- dist_empirical(x, positive = TRUE)
d_exp <- dist_exponential()
plot_distributions(
  empirical = d_emp,
  theoretical = d_exp,
  estimated = d_exp,
  with_params = list(
    theoretical = list(rate = rate),
    estimated = list(rate = 1 / mean(x))
  ),
  .x = seq(1e-4, 5, length.out = 100)
)
```

predict.reservr_keras_model
Predict individual distribution parameters

Description

Predict individual distribution parameters

Usage

```
## S3 method for class 'reservr_keras_model'
predict(object, data, as_matrix = FALSE, ...)
```

Arguments

object	A compiled and trained <code>reservr_keras_model</code> .
data	Input data compatible with the model.
as_matrix	Return a parameter matrix instead of a list structure?
...	ignored

Value

A parameter list suitable for the `with_params` argument of the distribution family used for the model. Contains one set of parameters per row in `data`.

Examples

```
if (interactive()) {
  dist <- dist_exponential()
  params <- list(rate = 1.0)
  N <- 100L
  rand_input <- runif(N)
  x <- dist$sample(N, with_params = params)

  tf_in <- keras3::layer_input(1L)
  mod <- tf_compile_model(
    inputs = list(tf_in),
    intermediate_output = tf_in,
    dist = dist,
    optimizer = keras3::optimizer_adam(),
    censoring = FALSE,
    truncation = FALSE
  )

  tf_fit <- fit(
    object = mod,
    x = k_matrix(rand_input),
    y = x,
    epochs = 10L,
    callbacks = list(
      callback_debug_dist_gradients(mod, k_matrix(rand_input), x)
    )
  )

  tf_preds <- predict(mod, data = k_matrix(rand_input))
}
```

Description

Determines the probability that claims occurring under a Poisson process with arrival intensity expo and reporting delay distribution dist during the time between t_min and t_max are reported between tau_min and tau_max.

Usage

```
prob_report(
  dist,
  intervals,
  expo = NULL,
  with_params = list(),
  .tolerance = .Machine$double.eps^0.5,
  .max_iter = 100L,
  .try_compile = TRUE
)
```

Arguments

<code>dist</code>	A reporting delay Distribution, or a compiled interval probability function.
<code>intervals</code>	A data frame with columns xmin, xmax, tmin, tmax. Claims occur within [xmin, xmax] and be reported within [tmin, tmax].
<code>expo</code>	Poisson intensity. If given, must be a vectorised function that yields the intensity of the claim arrival process at a specified time. <code>expo = NULL</code> is equivalent to a constant intensity function. <code>expo</code> is only relevant up to a multiplicative constant.
<code>with_params</code>	Parameters of <code>dist</code> to use. Can be a parameter set with different values for each interval. If <code>dist</code> is a compiled interval probability function, <code>with_params</code> can be a matrix instead.
<code>.tolerance</code>	Absolute element-wise tolerance.
<code>.max_iter</code>	Maximum number of iterations. The number of integration intervals will be at most <code>length(lower) * .max_iter</code> . Therefor the maximum number of function evaluations per integration interval will be $15 * .max_iter$.
<code>.try_compile</code>	Try compiling the distributions probability function to speed up integration?

Details

The reporting probability is given by

$$\begin{aligned} P(x + d \text{ in } [t_{\min}, t_{\max}] \mid x \text{ in } [x_{\min}, x_{\max}]) &= E(P(x + d \text{ in } [t_{\min}, t_{\max}] \mid x) \mid x \text{ in } [x_{\min}, x_{\max}]) / \\ P(x \text{ in } [x_{\min}, x_{\max}]) &= \int_{[x_{\min}, x_{\max}]} \exp(x) P(x + d \text{ in } [t_{\min}, t_{\max}]) dx = \int_{[x_{\min}, x_{\max}]} \exp(x) P(d \text{ in } [t_{\min} - x, t_{\max} - x]) dx / \int_{[x_{\min}, x_{\max}]} \exp(x) dx \end{aligned}$$

`prob_report` uses [integrate_gk\(\)](#) to compute the two integrals.

Value

A vector of reporting probabilities, with one entry per row of `intervals`.

Examples

```
dist <- dist_exponential()
ints <- data.frame(
  xmin = 0,
  xmax = 1,
  tmin = seq_len(10) - 1.0,
  tmax = seq_len(10)
)
params <- list(rate = rep(c(1, 0.5), each = 5))

prob_report(dist, ints, with_params = params)
```

quantile.Distribution *Quantiles of Distributions*

Description

Produces quantiles corresponding to the given probabilities with configurable distribution parameters.

Usage

```
## S3 method for class 'Distribution'
quantile(x, probs = seq(0, 1, 0.25), with_params = list(), ..., .start = 0)
```

Arguments

<code>x</code>	A Distribution.
<code>probs</code>	Quantiles to compute.
<code>with_params</code>	Optional list of distribution parameters. Note that if <code>x\$has_capability("quantile")</code> is false, <code>with_params</code> is assumed to contain only one set of parameters.
<code>...</code>	ignored
<code>.start</code>	Starting value if quantiles are computed numerically. Must be within the support of <code>x</code> .

Details

If `x$has_capability("quantile")` is true, this returns the same as `x$quantile(probs, with_params = with_params)`. In this case, `with_params` may contain separate sets of parameters for each quantile to be determined.

Otherwise, a numerical estimation of the quantiles is done using the density and probability function. This method assumes `with_params` to contain only one set of parameters. The strategy uses two steps:

1. Find the smallest and largest quantiles in `probs` using a newton method starting from `.start`.
2. Find the remaining quantiles with bisection using `stats::uniroot()`.

Value

The quantiles of `x` corresponding to `probs` with parameters `with_params`.

Examples

```
# With quantiles available
dist <- dist_normal(sd = 1)
qqs <- quantile(dist, probs = rep(0.5, 3), with_params = list(mean = 1:3))
stopifnot(all.equal(qqs, 1:3))

# Without quantiles available
dist <- dist_erlangmix(shapes = list(1, 2, 3), scale = 1.0)
my_probs <- c(0, 0.01, 0.25, 0.5, 0.75, 1)
qqs <- quantile(
  dist, probs = my_probs,
  with_params = list(probs = list(0.5, 0.3, 0.2)), .start = 2
)

all.equal(dist$probability(qqs, with_params = list(probs = list(0.5, 0.3, 0.2))), my_probs)
# Careful: Numerical estimation of extreme quantiles can result in out-of-bounds values.
# The correct 0-quantile would be 0 in this case, but it was estimated < 0.
qq[1L]
```

Description

Softmax for a vector `x` is defined as

Usage

`softmax(x)`

`dsoftmax(x)`

Arguments

x	A numeric vector or matrix
---	----------------------------

Details

$$s_i = \exp(x_i) / \sum_k \exp(x_k)$$

It satisfies `sum(s) == 1.0` and can be used to smoothly enforce a sum constraint.

Value

`softmax` returns the softmax of `x`; rowwise if `x` is a matrix.
`dsoftmax` returns the Jacobi-matrix of `softmax(x)` at `x`. `x` must be a vector.

Examples

```
softmax(c(5, 5))
softmax(diag(nrow = 5, ncol = 6))
```

<code>tf_compile_model</code>	<i>Compile a Keras model for truncated data under dist</i>
-------------------------------	--

Description

Compile a Keras model for truncated data under `dist`

Usage

```
tf_compile_model(
  inputs,
  intermediate_output,
  dist,
  optimizer,
  censoring = TRUE,
  truncation = TRUE,
  metrics = NULL,
  weighted_metrics = NULL
)
```

Arguments

<code>inputs</code>	List of keras input layers
<code>intermediate_output</code>	Intermediate model layer to be used as input to distribution parameters
<code>dist</code>	A Distribution to use for compiling the loss and parameter outputs
<code>optimizer</code>	String (name of optimizer) or optimizer instance. See <code>optimizer_*</code> family.
<code>censoring</code>	A flag, whether the compiled model should support censored observations. Set to FALSE for higher efficiency. <code>fit(...)</code> will error if the resulting model is used to fit censored observations.
<code>truncation</code>	A flag, whether the compiled model should support truncated observations. Set to FALSE for higher efficiency. <code>fit(...)</code> will warn if the resulting model is used to fit truncated observations.
<code>metrics</code>	List of metrics to be evaluated by the model during training and testing. Each of these can be: <ul style="list-style-type: none"> • a string (name of a built-in function),

- a function, optionally with a "name" attribute or
- a [Metric\(\)](#) instance. See the `metric_*` family of functions.

Typically you will use `metrics = c('accuracy')`. A function is any callable with the signature `result = fn(y_true, y_pred)`. To specify different metrics for different outputs of a multi-output model, you could also pass a named list, such as `metrics = list(a = 'accuracy', b = c('accuracy', 'mse'))`. You can also pass a list to specify a metric or a list of metrics for each output, such as `metrics = list(c('accuracy'), c('accuracy', 'mse'))` or `metrics = list('accuracy', c('accuracy', 'mse'))`. When you pass the strings 'accuracy' or 'acc', we convert this to one of `metric_binary_accuracy()`, `metric_categorical_accuracy()`, `metric_sparse_categorical_accuracy()` based on the shapes of the targets and of the model output. A similar conversion is done for the strings "crossentropy" and "ce" as well. The metrics passed here are evaluated without sample weighting; if you would like sample weighting to apply, you can specify your metrics via the `weighted_metrics` argument instead.

If providing an anonymous R function, you can customize the printed name during training by assigning `attr(<fn>, "name") <- "my_custom_metric_name"`, or by calling [custom_metric\("my_custom_metric_name", <fn>\)](#)

`weighted_metrics`

List of metrics to be evaluated and weighted by `sample_weight` or `class_weight` during training and testing.

Value

A `reservr_keras_model` that can be used to train truncated and censored observations from `dist` based on input data from `inputs`.

Examples

```
dist <- dist_exponential()
params <- list(rate = 1.0)
N <- 100L
rand_input <- runif(N)
x <- dist$sample(N, with_params = params)

if (interactive()) {
  tf_in <- keras3::layer_input(1L)
  mod <- tf_compile_model(
    inputs = list(tf_in),
    intermediate_output = tf_in,
    dist = dist,
    optimizer = keras3::optimizer_adam(),
    censoring = FALSE,
    truncation = FALSE
  )
}
```

`tf_initialise_model` *Initialise model weights to a global parameter fit*

Description

Initialises a compiled `reservr_keras_model` weights such that the predictions are equal to, or close to, the distribution parameters given by `params`.

Usage

```
tf_initialise_model(
  model,
  params,
  mode = c("scale", "perturb", "zero", "none")
)
```

Arguments

<code>model</code>	A <code>reservr_compiled_model</code> obtained by <code>tf_compile_model()</code> .
<code>params</code>	A list of distribution parameters compatible with <code>model</code> .
<code>mode</code>	An initialisation mode
scale	Initialise the biases according to <code>params</code> and the kernels uniform on [-0.1, 0.1] * bias scale.
perturb	Initialise the biases according to <code>params</code> and leave the kernels as is.
zero	Initialise the biases according to <code>params</code> and set the kernel to zero.
none	Don't modify the weights.

Value

Invisibly `model` with changed weights

Examples

```
dist <- dist_exponential()
group <- sample(c(0, 1), size = 100, replace = TRUE)
x <- dist$sample(100, with_params = list(rate = group + 1))
global_fit <- fit(dist, x)

if (interactive()) {
  library(keras3)
  l_in <- layer_input(shape = 1L)
  mod <- tf_compile_model(
    inputs = list(l_in),
    intermediate_output = l_in,
    dist = dist,
    optimizer = optimizer_adam(),
    censoring = FALSE,
```

```

        truncation = FALSE
    )
tf_initialise_model(mod, global_fit$params)
fit_history <- fit(
    mod,
    x = group,
    y = x,
    epochs = 200L
)

predicted_means <- predict(mod, data = as_tensor(c(0, 1), config_floatx()))
}

```

truncate_claims *Truncate claims data subject to reporting delay*

Description

Truncate claims data subject to reporting delay

Usage

```
truncate_claims(data, accident, delay, time, .report_col = "report")
```

Arguments

<code>data</code>	Full claims data including IBNR
<code>accident</code>	Accident times. May be an unquoted column name from <code>data</code> .
<code>delay</code>	Reporting delays. May be an unquoted column name from <code>data</code> .
<code>time</code>	Observation time (scalar number or one per claim). Claims with <code>accident + delay > time</code> will be truncated. Set <code>time = Inf</code> to only compute reporting times and perform no truncation.
<code>.report_col</code>	NULL or a column name to store the reporting time <code>report = accident + delay</code> .

Value

Truncated data. The reporting time is stored in a column named by `.report_col` unless `.report_col` is NULL. If both `.report_col` is NULL and `time` contains only Infs, a warning will be issued since data will be returned unchanged and no work will be done.

Examples

```

claims_full <- data.frame(
    acc = runif(100),
    repdel = rexp(100)
)
tau <- 2.0
truncate_claims(claims_full, acc, repdel, tau)

```

trunc_obs	<i>Define a set of truncated observations</i>
-----------	---

Description

If `x` is missing, both `xmin` and `xmax` must be specified.

Usage

```
trunc_obs(x, xmin = x, xmax = x, tmin = -Inf, tmax = Inf, w = 1)

as_trunc_obs(.data)

truncate_obs(.data, tmin_new = -Inf, tmax_new = Inf, .partial = FALSE)

repdel_obs(.data, accident, delay, time, .truncate = FALSE)
```

Arguments

<code>x</code>	Observations
<code>xmin, xmax</code>	Censoring bounds. If <code>xmin != xmax</code> , <code>x</code> must be NA.
<code>tmin, tmax</code>	Truncation bounds. May vary per observation.
<code>w</code>	Case weights
<code>.data</code>	A data frame or numeric vector.
<code>tmin_new</code>	New truncation minimum
<code>tmax_new</code>	New truncation maximum
<code>.partial</code>	Enable partial truncation of censored observations? This could potentially create inconsistent data if the actual observation lies outside of the truncation bounds but the censoring interval overlaps.
<code>accident</code>	accident time (unquoted, evaluated in <code>.data</code>)
<code>delay</code>	reporting delay (unquoted, evaluated in <code>.data</code>)
<code>time</code>	evaluation time (unquoted, evaluated in <code>.data</code>)
<code>.truncate</code>	Should claims reported after <code>time</code> be silently discarded? If there are claims reported after <code>time</code> and <code>.truncate</code> is FALSE, an error will be raised.

Details

Uncensored observations must satisfy `tmin <= xmin = x = xmax <= tmax`. Censored observations must satisfy `tmin <= xmin < xmax <= tmax` and `x = NA`.

Value

trunc_obs: A `trunc_obs` tibble with columns `x`, `xmin`, `xmax`, `tmin` and `tmax` describing possibly interval-censored observations with truncation

`as_trunc_obs` returns a `trunc_obs` tibble.

`truncate_obs` returns a `trunc_obs` tibble with possibly fewer observations than `.data` and updated truncation bounds.

`repdel_obs` returns a `trunc_obs` tibble corresponding to the reporting delay observations of each claim. If `.truncate` is `FALSE`, the result is guaranteed to have the same number of rows as `.data`.

Examples

```
N <- 100
x <- rexp(N, 0.5)

# Random, observation dependent truncation intervals
tmin <- runif(N, 0, 1)
tmax <- tmin + runif(N, 1, 2)

oob <- x < tmin | x > tmax
x <- x[!oob]
tmin <- tmin[!oob]
tmax <- tmax[!oob]

# Number of observations after truncation
N <- length(x)

# Randomly interval censor 30% of observations
cens <- rbinom(N, 1, 0.3) == 1L
xmin <- x
xmax <- x
xmin[cens] <- pmax(tmin[cens], floor(x[cens]))
xmax[cens] <- pmin(tmax[cens], ceiling(x[cens]))
x[cens] <- NA

trunc_obs(x, xmin, xmax, tmin, tmax)

as_trunc_obs(c(1, 2, 3))
as_trunc_obs(data.frame(x = 1:3, tmin = 0, tmax = 10))
as_trunc_obs(data.frame(x = c(1, NA), xmin = c(1, 2), xmax = c(1, 3)))
truncate_obs(1:10, tmin_new = 2.0, tmax_new = 8.0)
```

Description

Compute weighted moments

Usage

```
weighted_moments(x, w, n = 2L, center = TRUE)
```

Arguments

x	Observations
w	Case weights (optional)
n	Number of moments to calculate
center	Calculate centralized moments (default) or noncentralized moments, i.e. $E((X - E(X))^k)$ or $E(X^k)$.

Value

A vector of length n where the kth entry is the kth weighted moment of x with weights w. If center is TRUE the moments are centralized, i.e. $E((X - E(X))^k)$. The first moment is never centralized. The moments are scaled with $1 / \text{sum}(w)$, so they are not de-biased.

e.g. the second central weighted moment $\text{weighted_moment}(x, w)[2L]$ is equal to $\text{var}(\text{rep}(x, w)) * (\text{sum}(w) - 1) / \text{sum}(w)$ for integer w

See Also

Other weighted statistics: [weighted_quantile\(\)](#), [weighted_tabulate\(\)](#)

Examples

```
weighted_moments(rexp(100))
weighted_moments(c(1, 2, 3), c(1, 2, 3))
c(mean(rep(1:3, 1:3)), var(rep(1:3, 1:3)) * 5 / 6)
```

weighted_quantile *Compute weighted quantiles*

Description

Compute weighted quantiles

Usage

```
weighted_quantile(x, w, probs)
weighted_median(x, w)
```

Arguments

x	Observations
w	Case weights (optional)
probs	Quantiles to calculate

Value

A vector the same length as `probs` with the corresponding weighted quantiles of `x` with weight `w`. For integer weights, this is equivalent to `quantile(rep(x, w), probs)`

The weighted median of `x` with weights `w`. For integer weights, this is equivalent to `median(rep(x, w))`

See Also

Other weighted statistics: `weighted_moments()`, `weighted_tabulate()`

Examples

```
weighted_median(1:6)
weighted_median(1:3, c(1, 4, 9))
weighted_median(1:3, c(9, 4, 1))

weighted_quantile(1:3, c(1, 4, 9), seq(0.0, 1.0, by = 0.25))
quantile(rep(1:3, c(1, 4, 9)), seq(0.0, 1.0, by = 0.25))
```

`weighted_tabulate` *Compute weighted tabulations*

Description

Computes the sum of `w` grouped by `bin`. If `w` is missing the result is equivalent to `tabulate(bin, nbins)`

Usage

```
weighted_tabulate(bin, w, nbins = max(1L, bin, na.rm = TRUE))
```

Arguments

<code>bin</code>	An integer vector with values from 1L to <code>nbins</code>
<code>w</code>	Weights per entry in <code>bin</code> .
<code>nbins</code>	Number of bins

Value

A vector with length `nbins` where the `i`th result is equal to `sum(w[bin == i])` or `sum(bin == i)` if `w` is missing. For integer weights, this is equivalent to `tabulate(rep(bin, w), nbins)`.

See Also

Other weighted statistics: `weighted_moments()`, `weighted_quantile()`

Examples

```
weighted_tabulate(c(1, 1, 2))
weighted_tabulate(c(1, 1, 2), nbins = 3L)
weighted_tabulate(c(1, 1, 2), w = c(0.5, 0.5, 1), nbins = 3L)
```
